

# CHEMICAL EQUATIONS

- are the "recipes" in chemistry
- show the substances going into a reaction, substances coming out of the reaction, and give other information about the process

REACTANTS - materials that are needed for a reaction

PRODUCTS - materials that are formed in a reaction

COEFFICIENTS - give the ratio of molecules/atoms of one substance to the others

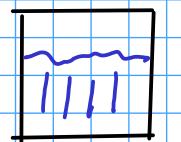

PHASE LABELS - give the physical state of a substance:

(s) -solid

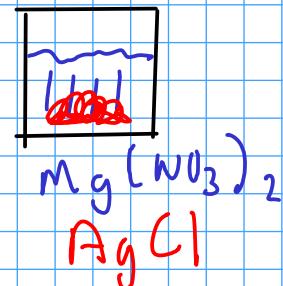

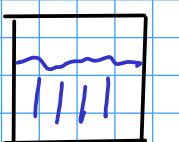

(l) - liquid

(g) - gas

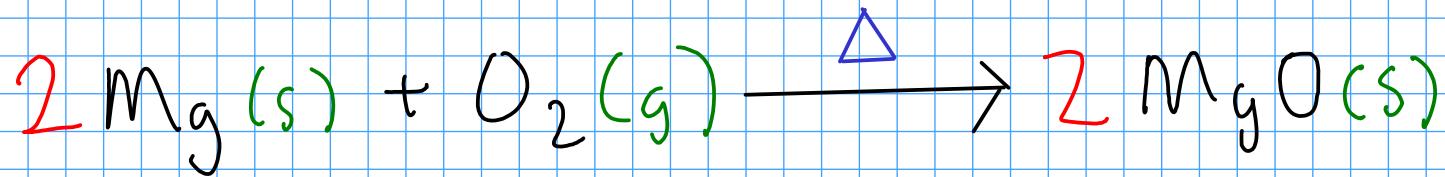

(aq) - aqueous. In other words, dissolved in water

+

## CHEMICAL EQUATIONS

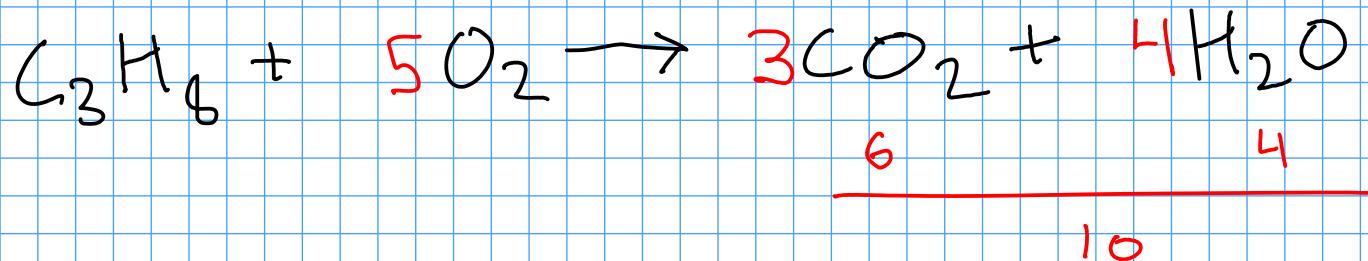

REACTION CONDITIONS - give conditions necessary for chemical reaction to occur. May be:

- $\Delta$  apply heat
  - catalysts - substances that will help reaction proceed faster
  - other conditions, such as required temperatures
- Reaction conditions are usually written above the arrow, but may also be written below if the reaction requires several steps or several different conditions

## COEFFICIENTS

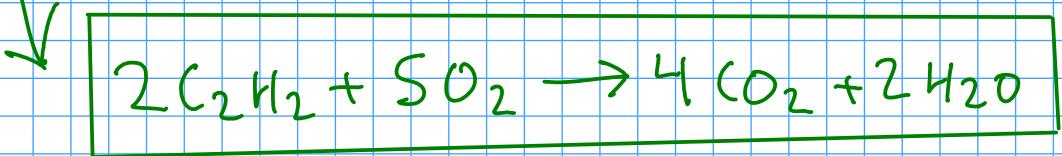

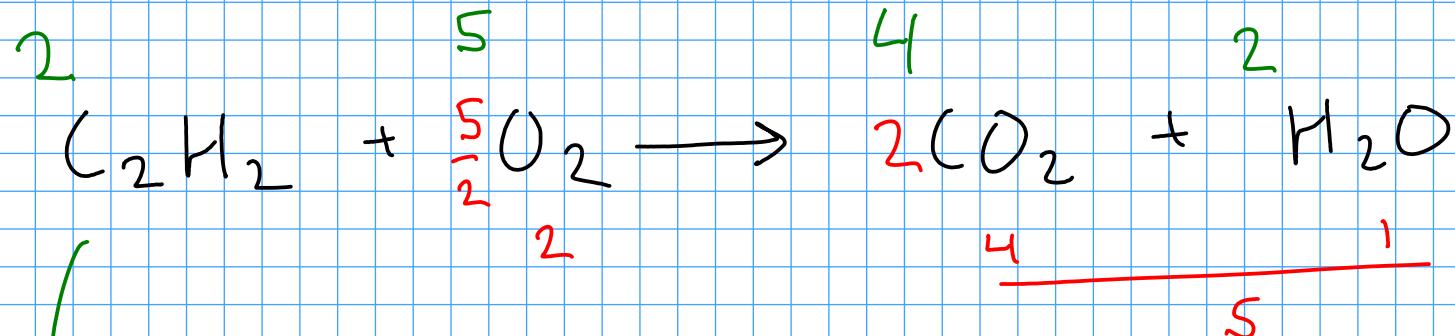

- Experimentally, we can usually determine the reactants and products of a reaction
- We can determine the proper ratios of reactants and products WITHOUT further experiments, using a process called BALANCING
- BALANCING a chemical equation is making sure the same number of atoms of each element go into a reaction as come out of it.
- A properly balanced chemical equation has the smallest whole number ratio of reactants and products.
- There are several ways to do this, but we will use a modified trial-and-error procedure.

## BALANCING

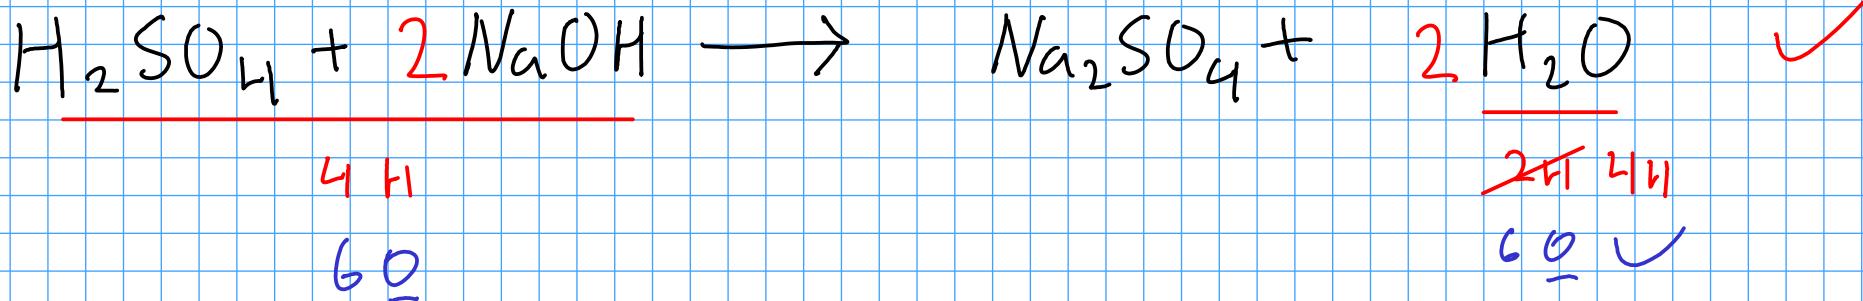

- (1) Pick an element. Avoid (if possible) elements that appear in more than one substance on each side of the equation.
- (2) Change the coefficients on substances containing this element so that the same number of atoms of the element are present on each side. CHANGE AS LITTLE AS POSSIBLE!
- (3) Repeat 1-2 until all elements are done.
- (4) Go back and quickly VERIFY that you have the same number of atoms of each element on each side. If you used any fractional coefficients, multiply each coefficient by the DENOMINATOR of your fraction.  
**Use SMALLEST WHOLE NUMBER RATIOS!**

## BALANCING

To get one oxygen atom from O<sub>2</sub>, you need HALF (1/2) of an O<sub>2</sub>. So to get FIVE oxygen atoms, you need 5/2 O<sub>2</sub>. To get rid of the 5/2, multiply EVERY coefficient by 2. That will give us the smallest whole number ratio!

## IDENTIFYING REACTIONS

You may see one or more of these signs when a chemical reaction occurs

- (1) - A change in temperature that can't be explained in another way.
- (2) - Emission of light that can't be explained in another way
- (3) - The formation of a solid - or PRECIPITATION - in a previously liquid solution. (Not a simple phase change!) or gas formation!
- (4) - Color change (not simply lightening of color caused by diluting a solution!)
