### CHEMICAL COMPOUNDS

- Dalton's theory does not mention this, but there is more than one way for atoms to come together to make chemical compounds!

- There are TWO common kinds of chemical compound, classified based on how the atoms in the compound are held together:

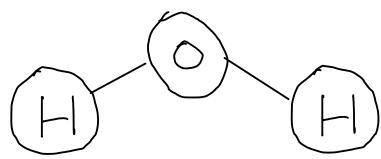

## MOLECULAR COMPOUNDS

# "I covalent bunds"

- form when atoms SHARE outer electrons with each other. This results in a set of connected atoms called a MOLECULE

Stick figure of a water ( $H_20$ ) molecule

is made up of

molecular

compounds

- usually form between nonmetals and other nonmetals or between nonmetals and metalloids Examples:  $H_2O$   $CO_2$   $CC_4$ CANDLE WAX

- some solid at room temperature. These solids tend to have low melting points. PULS is a solid, mp=180°C

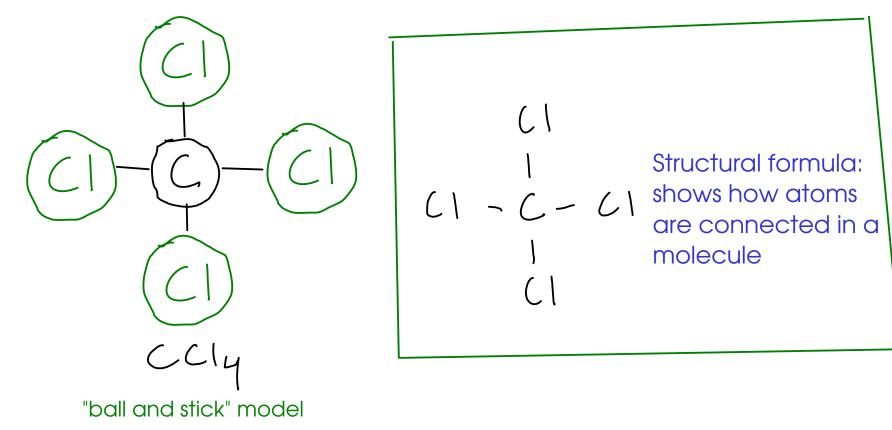

CO N205 PLIC

- many are liquids or gases at room temperature

H20, CCL4: liquids CO, CO2, N2O5: gases

- formula of a molecular compound represents the EXACT NUMBER OF ATOMS OF EACH ELEMENT in a single molecule of the compound

Example: Each molecule of  $CC|_{\mu}$  contains exactly one carbon atom and four chlorine atoms

### IONIC COMPOUNDS

- formed when atoms TRANSFER ELECTRONS between each other forming charged atoms, called IONS.

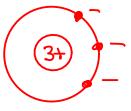

Two kinds of ions:

cation

) CATIONS: formed when an atom LOSES one or more electrons.

- overall, a cation has a POSITIVE charge, because it has more protons in the nucleus than electrons in the electron cloud

- usually formed by METALS, but occasionally hydrogen will also form a cation

lose one electron

(3+) • -

Overall charge: 0

Overall charge: +1

ANIONS: formed when an atom GAINS one or more electrons

- overall, an anion has a NEGATIVE charge, because it has more electrons in the electron cloud than protons in the nucleus

- usually formed by NONMETALS

### IONIC COMPOUNDS

- USUALLY form from metals combining with nonmetals, or from metals combining with metalloids

Examples: NaCl MgCl NaOH  

$$Ca(OH)_2$$
 NaOH  
 $Fe_2O_3$  FeO

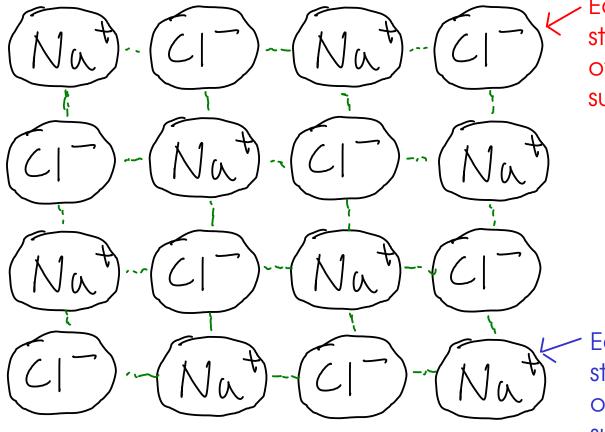

- almost always solid at room temperature, and usually have relatively high melting points

All of the above are solids at room temperature. NaCl has a melting point of 801 C.

- as solids, do not conduct electricity. If dissolved in water (some do not dissolve significantly in water), will form a solution that conducts electricity.

### IONIC COMPOUNDS

- ionic compounds are held together by ELECTROSTATIC INTERACTIONS (in other words, the attraction between oppositely charged ions!)

Each chloride ion is strongly attracted to ALL of the sodium ions surrounding it!

Each sodium ion is strongly attracted to ALL of the chlorine atoms surrounding it!

There are no "molecules" in ionic compounds - in the sense that you can't point to a discrete unit of atoms that are connected to only each other

#### IONIC FORMULAS

- since there are no "molecules", an ionic formula cannot describe how many and what kinds of atoms are in a molecule!

- all ionic compounds are observed to be (overall) electrically neutral, so the IONS they contain must be present in such a way that the charges BALANCE EACH OTHER

- an ionic formula gives the <u>SMALLEST WHOLE NUMBER RATIO OF</u> CATION TO ANION in the ionic compound

Na<sup>+</sup> 
$$C_{1}^{-}$$
 make NaCl (1:1 ratio)  
 $C_{a}^{2+}$   $C_{1}^{-}$  make  $C_{a}C_{12}$  (1:2 ratio)  
 $N_{a}^{+}$   $N_{3}^{3-}$  make  $N_{u_{3}}N$  (3:1 ratio)  
 $F_{e}^{3+}$   $O_{2}^{2-}$  make  $F_{e_{2}}O_{3}$  (2:3 ratio)
