

Bohr's model didn't account for electron-electron interactions (which didn't exist in HYDROGEN)

- To account for this added complexity, a more sophisticated model had to be devised: QUANTUM THEORY. Quantum theory is the modern picture of the atom and its electron cloud.

SHELLS, SUBSHELLS, AND ORBITALS

- Bohr's model predicted that energy levels (called SHELLS) were enough to describe completely how electrons were arranged around an atom. But there's more to it!

SHELL: Equivalent to Bohr's energy levels. Electrons in the same SHELL are all the same distance from the nucleus. They all have SIMILAR (but not necessarily the SAME) energy.

- Shells are numbered (1-... - Elements on the periodic table have shells numbered from 1 to 7)

- Higher numbers correspond to greater distance from the nucleus and greater energy, and larger size!

- Higher shells can hold more electrons than lower shells!

SUBSHELLS: Within a SHELL, electrons may move in different ways around the nucleus! These different "paths" are called SUBSHELLS

- SHAPES of regions of space that electrons are able to exist in.

Illustrations: p315-316

(a spherical region)

"p" subshell (a dumbbell shaped region)

"d" subshell

- Some atoms also have "f" subshells (not pictured)

See p 314-316 for nicer f=drawings of the subshells.

ORBITALS - are specific regions of space where electrons may exist

- The SHAPE of an orbital is defined by the SUBSHELL it is in

- The ENERGY of an orbital is defined by both the SHELL the orbital is in AND the kind of SUBSHELL it is in

- Each orbital may, at most, contain TWO ELECTRONS

ARRANGEMENT OF SHELLS, SUBSHELLS, AND ORBITALS

- Shells are numbered. Each shell can contain the same number of SUBSHELLS as its number:

1st shell: ONE possible subshell (s) 2nd shell: TWO possible subshells (s, p) 3rd shell: THREE possible subshells (s, p, d) 4th shell: FOUR possible subshells (s, p, d, f) ... and so on - Each subshell can contain one or more ORBITALS, depending on how many different ways there are to arrange an orbital of that shape around the nucleus.

Maximum 6 electrons in 3 orbitals

"s" subshell "p" subshell: Three possible orientations One possible orientation Maximum 2 electrons in 1 orbital

- There are five possible orbitals in a "d" subshell, and 7 possible orbitals in an "f" subshell!

Maximum 10 electrons in 5 orbitals (see p 316)

Maximum 14 electrons in 7 orbitals

ENERGY DIAGRAM

- We can map out electrons around an atom using an energy diagram:

5p 4d 5s 4p 3d **4**s 3р 3s "1s" means first shell, "s" subshell 2p 2s Each blank represents an ORIBITAL which can hold up to **TWO electrons 1**s

Let's look at some example atoms:

Magnesium: Z=12, 12 electrons

• Outermost electrons of magnesium "valence electrons". These electrons are involved in chemical bonding!

E N E R G Y

ELECTRON CONFIGURATION

- A shorthand way to write about electron arrangement around an atom.

Number of electrons in the subshell!

Aluminum has

Mg:
$$1s^2 2s^2 2p^6 3s^2$$

Al: $1s^2 2s^2 2p^6 3s^2 3p^6$
Valence electrons are the ones in the outermost
SHELL, not just the last subshell. Aluminum has
THREE valence electrons.

"s" block: last electron in these atoms is in an "s" orbital! "p" block: last electron in these atoms is in a "p" orbital! "d" block: last electron is these atoms is in a "d" orbital - To write an electron configuration using the periodic table, start at hydrogen, and count up the electrons until you reach your element!

Example: Phosphorus (P): $1 s^{2} 2 s^{2} 2 \rho^{6} 3 s^{2} 3 \rho^{3}$

 Phosphorus has FIVE valence electrons (all the electrons in the OUTER SHELL)

EXAMPLES: Remember - valence electrons are ALL of the $[s^{2}2s^{2}2e^{5}]$ electrons in the outermost SHELL! (may have more than one SUBSHELL)! s |s²2s²2p⁶3s²3p⁴ TITANIUM is a transition metal that commonly forms either +2 or +4 cations. The 4s electrons are lost when the +2 ion forms, while the 4s AND 3d electrons are lost to form the +4! C_{1} $] s^{2} 2 s^{2} 2 \rho^{6} 3 s^{2} 3 \rho^{5}$ You can order the subshells in numeric order OR CNe]3523pS / in filling order Ti 15225220635230631245 or 15252206353p6452312 $05(AC)3a^{2}4s^{2}$ se 1s²2s²2p⁶3s²3p⁶3a¹⁰4s²4p⁴ or [Ar]3104524p4 Noble gas core notation. Use the previous noble gas on the table, then add the electrons that it doesn't have to the end. Kr [Ar] 3 d" 4524p6

You are responsible for writing electron configurations up to Z=18, Argon. These are here to illustrate other points!

PERIODIC TRENDS

- Some properties of elements can be related to their positions on the periodic table.

ATOMIC RADIUS

- The distance between the nucleus of the atoms and the outermost shell of the electron cloud.

- Relates to the size of the atom.

- As you go DOWN A GROUP (\downarrow), the atomic radius INCREASES.

- Why? As you go down a period, you are ADDING SHELLS!

- As you go ACROSS A PERIOD (\longrightarrow), the atomic radius DECREASES

... so fluorine's outer shell is pulled closer to the nucleus than lithium's!

IONIZATION ENERGY (or FIRST IONIZATION ENERGY)

- The amount of energy required to remove a single electron from the outer shell of an atom.

- Relates to reactivity for metals. The easier it is to remove an electron, the more reactive the metal.

- As you go DOWN A GROUP (/), the ionization energy DECREASES.

- Why? As you go down a period, you are ADDING SHELLS. Since the outer electrons are farther friom the nucleus and charge attraction lessens with distance, this makes electrons easier to remove as the atoms get bigger!

- As you go ACROSS A PERIOD (\longrightarrow), the ionization energy INCREASES.

... since fluorine's outer electrons are held on by a larger effective charge, they are more difficult to remove than lithium's.

LARGER SMALLER RADIUS IONIZATION ENERGY
