

67 COLLIGATIVE PROPERTIES

- properties unique to solutions.
- depend only on the CONCENTRATION of a solution and not the IDENTITY of the solute**

**ionic solutes: Remember that they dissociate into MULTIPLE IONS!

① Freezing point depression

- The freezing temperature of a SOLUTION gets lower as the CONCENTRATION of a solution increases.

② Vapor pressure lowering

- The vapor pressure of a solution (pressure of solvent vapor over a liquid surface) goes DOWN as solution concentration goes UP

③ Boiling point elevation

- The boiling temperature of a solution increases as the concentration of the solution increases.

④ Osmotic pressure

- The pressure required to PREVENT the process of osmosis

FREEZING POINT DEPRESSION

$$\Delta T_f = K_f \times C_m$$

C_m concentration of solute (molality)

K_f Freezing point depression constant (for SOLVENT)

ΔT_f Freezing point depression: The amount the freezing temperature is LOWERED by the solute.

- Applications: In chemistry, this effect is often used to determine the molecular weight of an unknown molecule.

A solution of 2.500g of unknown dissolved in 100.0 g of benzene has a freezing point of 4.880 C. What is the molecular weight of the unknown?

$$K_{f, \text{benzene}} = 5.065 \text{ } ^\circ\text{C}/m, \quad T_{f, \text{benzene}} = 5.455 \text{ } ^\circ\text{C}$$

$$\Delta T_f = K_f \times \underbrace{C_m}_{\substack{\text{moles unknown} \\ \text{kg solvent}}}$$

$$\uparrow = 5.455 \text{ } ^\circ\text{C} - 4.880 \text{ } ^\circ\text{C} = 0.575 \text{ } ^\circ\text{C}$$

* We can calculate the MOLAL concentration of the solution based on the FREEZING POINT DEPRESSION

$$0.575 \text{ } ^\circ\text{C} = (5.065 \text{ } ^\circ\text{C}/m) C_m$$

$$0.1135241856 \text{ } m = C_m = \frac{\text{mol unknown}}{\text{kg benzene}}$$

unknown
benzene

Find moles unknown using mass of benzene and the molal concentration

$$0.1000 \text{ kg benzene} \times \frac{0.1135241856 \text{ mol unknown}}{\text{kg benzene}} = 0.01135241856 \text{ mol unknown}$$

Molecular weight is mass per mole, so ...

$$MW = \frac{\text{mass unknown}}{\text{mol unknown}} = \frac{2.500 \text{ g}}{0.01135241856 \text{ mol}} = \boxed{220 \text{ g/mol}}$$
