- The oldest model of acid-base chemistry!
- Only applicable to systems where WATER is the solvent!

ACIDS are substances that ionize in water to increase the concentration of HYDRONIUM ION

$$
\text { or, for simplicity: } \mathrm{HA} \stackrel{\mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{H}_{2} \mathrm{O}}{\sim} \mathrm{H}^{+}+\mathrm{A}^{-}}{ } \begin{aligned}
& \text { "Hydrogen ion" - doesn't } \\
& \begin{array}{l}
\text { really exist as a free ion in } \\
\text { water, but a convenient } \\
\text { simplification! }
\end{array}
\end{aligned}
$$

ARRHENIUS THEORY

BASES are substances that ionize in water to increase the concentration of HYDROXIDE ION

For soluble metal hydroxides:

$$
\mathrm{NaOH} \rightarrow \mathrm{Na}^{+}+\mathrm{OH}^{-}
$$

$$
\mathrm{MOH} \stackrel{\mathrm{H}_{2} \mathrm{O}}{\rightleftharpoons} \mathrm{M}^{+}+\frac{\mathrm{OH}^{-}}{L} \text { Hydroxide ion }
$$

For other Arrhenius bases:

$$
\mathrm{B}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{BH}^{+}+\mathrm{OH}^{-} \quad \text { ex: } \mathrm{NH}_{3}
$$

An Arrhenius acid base reaction can be represented by:

$$
\mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{OH}^{-} \rightleftharpoons 2 \mathrm{H}_{2} \mathrm{O} \quad \text { "neutralization" }
$$

or, using hydrogen ion instead of hydronium

$$
\mathrm{H}^{+}+\mathrm{OH}^{-} \rightleftharpoons \mathrm{H}_{2} \mathrm{O}
$$

## BRONSTED-LOWRY THEORY

- Bronsted-Lowry theory views acid-base reactions as PROTON TRANSFER reactions!

## ACIDS are PROTON DONORS

BASES are PROTON ACCEPTORS

A CONJUGATE PAIR is an acid and a base that differ by a proton!
... a few examples of conjugate pairs:

| Species | Conjugate |
| :---: | :---: |
| $\mathrm{N}_{2} \mathrm{H}_{2} \mathrm{~N}$ | $\mathrm{NH}_{4}^{+}$ |
| $\mathrm{H}_{2} \mathrm{O}$ | $\mathrm{HH}_{2}^{-}$ |
| $\mathrm{H}_{2} \mathrm{H}_{2} \mathrm{O}_{2}$ | $\mathrm{H}_{3}^{+}$ |
| $\mathrm{H}_{2}^{+}$ |  |

RED for acid
BLUE for base

A generic Bronsted-Lowrey acid. base reaction:

... you should be able to write the products of a Bronsted-Lowry acid-base reaction, identifying the CONJUGATE PAIRS

IN WATER...

$$
\begin{gathered}
+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3}^{+}+\mathrm{A}^{-} \\
\begin{array}{c}
\text { conjugate base } \\
\text { of } \mathrm{HA}
\end{array} \\
\text { acid }
\end{gathered}
$$

$$
\begin{aligned}
& \mathrm{B}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{BH}^{+}+\mathrm{OH}^{-} \\
& \text {base }
\end{aligned}
$$ of $B$

$$
\mathrm{NH}_{3}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \frac{\mathrm{NH}_{4}^{+}+\mathrm{OH}}{}{ }^{-} \text {Ammonia and water }
$$

In the red reactions, water functions as a base. In the blue reactions, water functions as a acid!

## LEWIS THEORY

- Lewis theory treats acid-base chemistry as ELECTRON-TRANSFER chemistry involving pairs of electrons
- Lewis acid-base reactions form new covalent bonds (of interest to organic chemists!)

ACIDS are ACCEPTORS of electron pairs
... this is why some METAL IONS, even though they contain no hydorgen ions, can exhibit ACIDIC character. Many metal ions can accept a pair of electrons to form a COMPLEX with a Lewis base! ex: $\mathrm{Ag}_{\mathrm{g}}\left(\mathrm{NH}_{3}\right)_{2}^{+}$
BASES are DONORS of electron pairs.
... so, Lewis bases have LONE PAIRS OF ELECTRONS in their Lewis structures

... In a Lewis acid-base reaction, electrons are donated from the Lewis base to the Lewis acid. This forms a new COVALENT BOND between the acid and the base.

Example: ammonia and water

$$
\mathrm{H}_{2} \mathrm{O}+: \mathrm{NH}_{3} \rightleftharpoons \mathrm{NH}_{4}^{+}+\mathrm{OH}^{-}
$$

$$
\text { Overall: } \mathrm{H}_{2} \mathrm{O}+\mathrm{NH}_{3} \rightleftharpoons \mathrm{NH}_{4}{ }^{+}+\mathrm{OH}^{-}
$$

- From Arrhenius to Lewis, the definitions get broader as you go along. In other woeds, the later definitions include MORE SUBSTANCES under the acid/base umbrella.

If something is an Arrhenius acid, it is also an acid in the Bronsted or Lewis picture. If something is an Arrhenius base, it is also a base in the Bronsted or Lewis picture.

All Bronsted acids are Lewis acids, and all Bronsted bases are Lewis bases.
... but not all Lewis acids/bases (like the metal ions) are Bronsted or Arrhenius acids/bases.

... We will primarily use the BRONSTED-LOWRY theory from this point in the course!

- Water self-ionizes!

$$
2 \mathrm{H}_{2} \mathrm{O} \underset{\text { or }}{\rightleftharpoons} \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{OH}^{-}
$$

$$
\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}^{+}+\mathrm{OH}^{-}
$$

This is an equilibrium reaction!

$$
K=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{H}_{2} \mathrm{O}\right]^{2}}(X)=\text { molar concentration of "X" }
$$

In aqueous solution, ( $\mathrm{H}_{2} \mathrm{O}$ ) is essentially constant, so we roll that into K.

$$
\mathrm{K}_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-14}
$$

- The self-ionization of water has a small equilibrium constant. What does this imply?

THE CONCENTRATION OF HYDROXIDE AND HYDRONIUM ION
IN PURE WATER IS VERY SMALL!

How small?

$$
2 \mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{OH}^{-}
$$

_-In pure water, the concentration of hydroxide and hydronium must be equal, since they are formed at the same time and at the same ratio from the ionization reaction of water.

$$
K w=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]=1 \times 10^{-14}
$$

Solve... Let $x=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{OH}^{-}\right]$

$$
\begin{aligned}
(x)(x) & =1.0 \times 10^{-14} \\
x^{2} & =1.0 \times 10^{-14} \\
x & =1.0 \times 10^{-7} \mathrm{M}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{OH}^{-}\right]
\end{aligned}
$$

- "p" notation helps us deal with the very small numbers we encounter when working with acids, bases, and water.
- based on log base 10

On a calculator, use

$$
\text { "p" means }-10 g_{10}
$$

$\square$

So,

$$
\begin{aligned}
& \rho H=-\log _{10}\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \\
& \rho O H=-\log _{10}\left[\mathrm{OH}_{3} \mathrm{O}^{+}\right]=10^{-\mathrm{pH}} \\
& {\left[\mathrm{OH}^{-}\right]=10^{-\mathrm{pOH}}}
\end{aligned}
$$

"p" NOTATION

- Apply "p" notation to the water self-ionization reaction!

$$
\begin{gathered}
K_{W}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.00 \times 10^{-14} \\
\text { becomes } \ldots \\
K_{w}=p H+p O H=14.00
\end{gathered}
$$

Taking the "p" (negative log base ten) of the equilibrium constant is often used for BUFFER SOLUTIONS, which we'll discuss later!

ACIDITY AND ALKALINITY

- At $\mathrm{pH}=7, \mathrm{pH}=\mathrm{pOH}$. The solution is considered NEUTRAL

$$
\square \mathrm{Also},\left[\mathrm{H}^{+}\right]=\left[\mathrm{OH}^{-}\right]!
$$

- At $\mathrm{pH}<7, \mathrm{pH}<\mathrm{pOH}$. The solution is considered ACIDIC

$$
L \text { Also, }\left[\mathrm{H}^{+}\right]>\left[\mathrm{OH}^{-}\right]!
$$

- At $\mathrm{pH}>7, \underline{\mathrm{pH}}>\mathrm{pOH}$. The solution is considered ALKALINE (BASIC)

$$
\square \text { Also, }\left[\mathrm{H}^{+}\right]<\left[\mathrm{OH}^{-}\right]!
$$

The pH scale...

$$
\begin{aligned}
& \left|\begin{array}{c}
\text { ACIDIC } \\
{\left[\mathrm{H}^{+}\right]>1 \times 10^{-7}}
\end{array} \frac{\text { ALKALINE }}{\left[\mathrm{H}^{+}\right]<1 \times 10^{-7}}\right| \\
& \mathrm{pH}=0 \\
& \mathrm{pH}=7 \\
& \mathrm{pH}=14 \\
& \text { NEUTRAL } \\
& {\left[\mathrm{H}^{+}\right]=1 \times 10^{-7}}
\end{aligned}
$$

pH AND TEMPERATURE

$$
p K_{w}=p H+p O H=14.00
$$

This equation is valid at room temperature, specifically $25^{\circ} \mathrm{C}$.
Equilibrium constants depend on TEMPERATURE, and change with temperature.
So, the "neutral" pH (where the concentration of hydroxide and hydronium ions are equal) CHANGES with changing temperatures

This change is important at temperatures greatly different from $25^{\circ} \mathrm{C}$.
As an example, consider average "normal" human body temperature: $37^{\circ} \mathrm{C}$

$$
\begin{array}{ll}
\text { At } 37^{\circ} \mathrm{C}, & \text { ptrw }=13.60 \\
& \text { pH of neutral solution }=6.8
\end{array}
$$

ACID-BASE EQUILIBRIUM IN WATER

- Like other ELECTROLYTES, acids and bases IONIZE to some extent in water
- STRONG electrolytes ionize completely. Acids and bases that ionize completely in water are called STRONG ACIDS and STRONG BASES
- WEAK electrolytes ionize partially, remaining mostly non-ionized. Acids and bases that ionize only partially in solution are called WEAK ACIDS and WEAK BASES.
- Most acids and bases are WEAK!

Common strong acids
HCl
$\mathrm{HNO}_{3}$

$$
\mathrm{H}_{2} \mathrm{SO}_{4} \text { (only } 1^{\text {st }} \text { proton) }
$$

HBr HI

Common strong bases

$$
\left.\begin{array}{l}
\mathrm{NaOH} \\
\mathrm{KOH}
\end{array}\right] \begin{aligned}
& \text { alkali metal } \\
& \text { hydroxides } \\
& \text { (GroupIA) }
\end{aligned}
$$

## SIMPLE pH CALCULATIONS: STRONG ELECTROLYTES

- With strong acids and bases, the acid or base completely ionizes in water. So, we only have to worry about the effect of the acid or base on the water equilibrium itself.
- Since the equilibrium constant for the self-ionization of water is so small, the strong acid or base will overpower the hydronium (for acids) or hydroxide (for bases) produced by the water.

$$
\mathrm{H}_{2} \mathrm{O}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{OH}^{-} ; \mathrm{K}_{w}=1.0 \times 10^{-14}
$$

Consider a solution of 0.025 M nitric acid (a strong acid):

$$
\mathrm{HNO}_{3}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{NO}_{3}^{-}
$$

Assume that all of the hydronium ion present at equilibrium comes from the acid (contribution of the water equilibrium itself is minimal)

$$
\begin{aligned}
& \text { So, }\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\text {numinal }\left[\mathrm{HNO}_{3}\right]= \\
& \mathrm{pH}=-\log _{10}(0.025)=1.6 \mathrm{O}
\end{aligned}
$$

What would the hydroxide ion concentration be?

$$
\begin{aligned}
{\left[\mathrm{H}_{3} \mathrm{O}+\right]\left[\mathrm{OH}^{-}\right] } & =1.0 \times 10^{-14} \\
(0.025]\left[\mathrm{OH}^{-}\right] & =1.0 \times 10^{-14} \\
{\left[\mathrm{OH}^{-}\right] } & =4.0 \times 10^{-13} \mathrm{M}
\end{aligned}
$$

... this equals the amount of water that dissociates!
$0.025 \mathrm{M} \mathrm{H}_{3} \mathrm{O}^{+}$ For logarithms, the places AFTER the decimal point are significant digits, while the numbers in front of the dedimal point are not (they're the exponent in the original number.)

Consider a solution of 0.0125 M sodium hydroxide (a strong base):
Again, let's assume that the base provides all of the hydroxide in solution

$$
\begin{aligned}
\mathrm{NaOH} & \rightarrow \mathrm{Na}^{+}+\mathrm{OH}^{-} \\
{[\mathrm{OH}-] } & =\text { nominal }[\mathrm{NaOH}]=0.0125 \mathrm{M} \mathrm{OH}^{-} \\
\mathrm{POH} & =-\log _{10}(0.012 \delta)=1.90
\end{aligned}
$$

... now change pOH to pH so we can compare this to the acid problem we
just solved:

$$
\begin{aligned}
p H+p o H & =14.00 \\
p H+1.40 & =14.00 \\
p H & =12.10
\end{aligned}
$$

Let's find the concentration of the hydronium ion, since that concentration equals the amount of water that ionized (and the amount of hydroxide produced by the water equilibrium). We assumed that this number was much less than 0.0125

$$
\begin{aligned}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] } & =10^{-12.10} \\
& =7.9 \times 10^{-13} \mathrm{M}
\end{aligned}
$$

... which is indeed much less than 0.0125
