## ${ }^{64}$ MOLARITY and the other concentration units

- To convert between molarity and the other three concentration units we've studied, you have to know more about the solution. For example:

To perform this conversion, you can assume a liter of solution, which will give you the number of moles present. But you've then got to have a way to convert the volume of SOLUTION to the mass of the SOLVENT. How?

* You need DENSITY (which depends on temperature). The density of the solution will allow you to find the total mass of the solution.

If you subtract out the mass of the SOLUTE, then what you have left is the mass
7 of the SOLVENT. Express that in kilograms, and you have all the information you need to find molality!

You'll run into the same situation when you use any of the other mass or mole

* based units. DENSITY is required to go back and forth between MOLARITY and these units.
${ }^{65}$ Example: If a solution is 0.688 m citric acid, what is the molar concentration $(\mathrm{M})$ of the solution?
The density of the solution is $1.049 \mathrm{~g} / \mathrm{mL}$

$$
\begin{aligned}
& \mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7} ; 192.12 \mathrm{~s} / \mathrm{mol} \text { " } \mathrm{CA}^{\prime} \\
& \underset{\text { Kg solvent }}{0.688 \mathrm{~mol} C A} \longrightarrow \frac{? \operatorname{mol} C A}{? \text { L solution }} \\
& \text { molality (definition) } \\
& \text { molarity }
\end{aligned}
$$

1 - Assume a basis of 1 kg of solvent. In each kilogram of solvent, we know that there are 0.688 mol CA.

2- We need to find VOLUME of solution. We know the density of the SOLUTION, but at the moment we know the mass of the SOLVENT. To use the density, we need to know the mass of the SOLUTION. We meed to add the mass of SOLUTE (CA) to the mass of the solvent to get the mass of solution.

$$
\begin{aligned}
& 0.688 \text { mol/ } \mathrm{A} \times \frac{192.125 \mathrm{~g} C \mathrm{~A}}{\text { moll } C \mathrm{~A}}=132.182 \mathrm{~g}(\mathrm{~A} \\
& \text { mass solution }=1000 \mathrm{~g} \text { solvent +132.182 } \mathrm{g} C \mathrm{~A}=1132.182 \mathrm{~g} \text { solution }
\end{aligned}
$$

Find volume (using density):

$$
1132.182 \mathrm{~g} \text { Solution } \times \frac{\mathrm{mL}}{1.049 \mathrm{~g}} \times \frac{10^{-3 \mathrm{~L}}}{\mathrm{~mL}}=1.079296 \mathrm{~L}
$$

Molarity $=$ moles CA $/ \mathrm{L}$ solution :

$$
\frac{0.688 \mathrm{~mol} \mathrm{CA}}{1.079296 \mathrm{~L}}=0.637 \mathrm{MCA}
$$

${ }^{66}$ An aqueous solution is $8.50 \%$ ammonium chloride by mass. The density of the solution is $1.024 \mathrm{~g} / \mathrm{mL}$ Find: molality, mole fraction, molarity.
$\mathrm{NH}_{4} \mathrm{Cl}: 53.491 \mathrm{~g} 1 \mathrm{~mol} \mathrm{H}_{2} 0: 18.016 \mathrm{~g} 1 \mathrm{~mol}$
Find molality:

Find mol ammonium chloride using formula weight

$$
8.50 \mathrm{~g} \mathrm{NHyCl} \times \frac{\mathrm{mol} \mathrm{NHGCl}}{53.491 \mathrm{gNHHCl}}=0.1589052364 \mathrm{~mol} \mathrm{NH} 4 \mathrm{Cl}
$$

Find mass water by subtraction, then convert to kg

$$
10 \mathrm{O} \text { y solution- }-8.5 \mathrm{~g} \mathrm{~g} \mathrm{NH}_{4} \mathrm{Cl}=91.50 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}=0.0915 \operatorname{trg~} \mathrm{H}_{2} \mathrm{O}
$$

Molality:

$$
\frac{0.1589052364 \mathrm{~mol} \mathrm{NH}}{4} \mathrm{Cl}, 1.74 \mathrm{~m} \mathrm{NH}_{4} \mathrm{Cl}
$$

Find mole
fraction: $\frac{8 . \mathrm{SO}_{\mathrm{g}} \mathrm{NH}_{4} \mathrm{Cl}}{10 \mathrm{O} \mathrm{g}_{\text {solution }}} \longrightarrow \frac{{\mathrm{mol} \mathrm{NH}_{4} \mathrm{Cl}}_{\text {mol } \mathrm{NH}_{4} \mathrm{Cl}+\mathrm{mol} \mathrm{H}_{2} \mathrm{O}}^{\text {mole fraction }}}{}$
We already know the mol ammonium chloride, so all we need to find is the number of moles of water. We've already found the mass of water in the solution, so just convert to moles with the formula weight.

67
An aqueous solution is $8.50 \%$ ammonium chloride by mass. The density of the solution is $1.024 \mathrm{~g} / \mathrm{mL}$ Find: molality, mole fraction, molarity.

$$
\begin{aligned}
& \mathrm{NH}_{4} \mathrm{Cl}: 53.491 \mathrm{~g} 1 \mathrm{~mol} \mathrm{H}_{2} 0: 18.016 \mathrm{~g} 1 \mathrm{~mol} \\
& 91.50 \mathrm{~g} \mathrm{H} \mathrm{H} \mathrm{O} \times \frac{\mathrm{mol} \mathrm{H} \mathrm{O}}{18.016 \mathrm{~g} \mathrm{H}} \mathrm{O} \mathrm{O}=5.078818828 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O} \\
& X_{\mathrm{NH}_{4} \mathrm{Cl}}=\frac{0.15890 \mathrm{SL} 364 \mathrm{~mol} \mathrm{NH}_{4} \mathrm{Cl}}{0.15890 \mathrm{SL} 364 \mathrm{~mol} \mathrm{NH} \mathrm{Cl}+5.078818828 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}} \\
& X_{N H_{4} C l}=0.0303 \text { If we want to know water, } \text { water }=1 \text { - ammonium chloride }
\end{aligned}
$$

We already know moles ammonium chloride from previous work, so we need to find out the VOLUME IN LITERS of that 100 g of solution.

$$
\begin{aligned}
& 100 \mathrm{~g} \text { solution } \times \frac{\mathrm{mL}}{1.024 \mathrm{~g}} \times \frac{10^{-3} \mathrm{~L}}{\mathrm{~mL}}=0.09765625 \mathrm{~L} \\
& \frac{0.1589052364 \mathrm{~mol} \mathrm{NH} \mathrm{Cl}}{0.09765625 \mathrm{~L}}=1.63 \mathrm{~N} \mathrm{NHyLl}
\end{aligned}
$$

- Let's look at how things dissolve into water, since aqueous solutions are quite common.

$$
\stackrel{\text { sucrose (table sugar) }}{\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}} \mathrm{O}_{11}(\mathrm{~s}) \stackrel{\mathrm{H}_{22}}{\rightleftarrows} \mathrm{H}_{22} \mathrm{O}_{11}\left(\mathrm{a}_{9}\right)
$$

... what happens?

- Water molecules pull the sugar molecules out of the sugar crystal and into solution.
- Attractions between sugar molecules and water allow this to happen.
- The solubility of the sugar depends on how well water and sugar interact (HYDRATION) versus how well the sugar molecules are held in the crystal (LATTICE ENERGY)
- "like dissolves like": Substances held together by similar (or at least compatible) kinds of attractive forces can dissolve in each other. Substances that are held together by very different kinds of attractive forces will not dissolve in one another!

## Consider WATER:

Water mixes well with other substances that can hydrogen bond, like ETHANOL!

Water can dissolve polar substances! (SUCROSE is polar!)

J,
Since IONIC BONDS are

SMALL (little London force) $\downarrow$
large and/or nonpolar solutes do not dissolve well in water!
(example: OILS and WAXES) also interactions between opposite charges (You can think of an ionic bond here as an extreme case of dipole-dipole interaction), many IONIC SUBSTANCES will also dissolve in water!

$$
\mathrm{Na}^{+}-\mathrm{Cl}^{-}
$$

- MOLECULAR solutions:

Contain MOLECULES dissolved in one another.
(1) - Any mixture of GASES

- all gases mix with one another, since gas molecules (effectively) do not interact with one another.
(2) - Liquids
- Liquids dissolve well in one another only if they are held together by similar kinds of forces
(3) - Solids and liquids
- MOLECULAR SOLIDS will dissolve well in liquids if they are held together by similar forces.
- IONIC SOLIDS will sometimes dissolve in POLAR liquids, but not in nonpolar liquids
- COVALENT NETWORK solids don't generally dissolve well in other substances
- form when ions from IONIC SUBSTANCES interact with POLAR solvents often WATER.

- The solubility of an ionic compound depends on whether HYDRATION (attraction of water molecules for an ion) is greater than LATICE ENERGY - the attrraction of ions in a crystal lattice for one another..
- SMALLER IONS are usually easier to enclose in water than larger ones, and ions with larger charges are attracted to water molecules.
- But solubility is also determined by LATTICE ENERGY - which holds the solid ionic compound together. Ions with high charges tend to be strongly attracted to other ions in a crystal, meaning lattice energy is high. Smaller ions also tend to have higher lattice energies. Lattice energy and hydroation are competing trends!
