NAMING IONIC COMPOUNDS

- The name of the compound is based on the name of the ions in the compound
- Cation first, anion second (drop the word "ion")

Examples:

magnesium hydroxide

sodium sulfide

beryllium bromide

Fe
$$_{2}$$
 O $_{3}$ Fe³⁺ $_{\overline{+6}}$ iron(III) oxide

$$\frac{CuD}{+2-7}$$
copper(II) oxide

$$\begin{array}{cccc}
\text{Cu} & & & & \\
\text{Cu} & & & \\
\text{Copper(I) oxide} & & & & \\
\end{array}$$

Remember to include the Roman numeral for CHARGE in the name of transition metal compounds!

NAMING IONIC COMPOUNDS

(NH4)25

ammonium sulfide

Fe (O_3 Fe²⁺ (O_3 iron(II) carbonate O_3 O_3

 $T_i S_2$ T_i titanium(IV) sulfide

T: 44 -4

 $(\alpha(N0_3)_2$ calcium nitrate

Bas $(P04)_2$ barium phosphate

Spelling matters!

barium phosphide

- The name of an ionic compound is made of the names of the CATION and ANION in the compound.
- To get the FORMULA, you must figure out the SMALLEST RATIO of cation to anion that makes the charges balance out

Examples:

iron(III) carbonate

$$Fe^{3t} (O_3^{2-} Fe^{3t} (O_3^{2-} Ge^{3t} (O_3^{2-} Ge^{3t} Ge^{2t} Ge^{2t}))$$

$$Fe_2 ((O_3^{2-} Ge^{2t} Ge$$

potassium sulfide

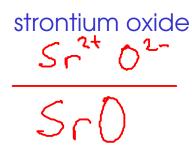

calcium bromide

DETERMINING IONIC FORMULAS

sodium sulfate Na+ SDy2 Na+

tin(II) phosphate

barium hydroxide

chromium(III) nitrate

titanium(IV) chloride

chromium(III) nitrite (r3+ NO2NO2NO2(r(NO2)3 chromium(III) nitride (r3+ N3-

titanium(IV) oxide

CrN

If your formula contains more than one polyatomic ion, you NEED to put the polyatomic ion in parenthesis!

MOLECULAR COMPOUNDS

- There are several kinds of molecular compound. We will learn to name two simple but important classes

BINARY MOLECULAR COMPOUNDS

- molecular compounds containing only two elements

2 ACIDS

- molecular compounds that dissolve in water to release $H^{\mathcal{T}}$ ions
- corrosive to metals (react with many to produce hydrogen gas)
- contact hazard: can cause chemical burns to eyes and skin
- sour taste
- turn litmus indicator RFD
- two kinds of acids:

usually Group VIIA

- contain hydrogen and one other element

- contain hydrogen, OXYGEN, and another element

BINARY MOLECULAR COMPOUNDS

- Named based on the elements they contain, plus prefixes to indicate the number of atoms of each element in each molecule

FIRST ELEMENT

- Add a GREEK PREFIX to the name of the element.
- Omit the "MONO-" (1) prefix if there is only one atom of the first element

SECOND ELEMENT

- Add a GREEK PREFIX to the STEM NAME of the element
- Add the suffix <u>"-ide"</u> (as if you were naming an anion)
- DO NOT omit the "mono-" prefix if there is only one atom of the second element

Examples:

(1207

(D)

C 0 2

boron trifluoride

dichlorine hept(a)oxide

carbon monoxide

carbon dioxide

(But we call it by its common name - water!)

carbon tetrachloride

iodine trichloride

dinitrogen tetrafluoride

magnesium CHLORIDE, not magnesium dichloride. Why? Magnesium chloride is IONIC, and should be named using the system we already learned for ionic compounds. (How can we tell? Generally, metal/nonmetal compounds are IONIC.)

ACIDS

(I) BINARY ACIDS

- named after the element (other than hydrogen) they contain
- common binary acids include a Group VIIA element
- named: "Hydro-" + STEM NAME OF ELEMENT+ "-ic acid"

```
Four common binary acids

HCI: hydrofluoric acid

HCI: hydrobromic acid

HCI: hydroiodic acid
```
