- Solids may also be classified by structure. A more in-depth look at solids is something you would find in a materials science class, but we'll discuss two broad categories of solid materials.

(1) AMORPHOUS SOLIDS

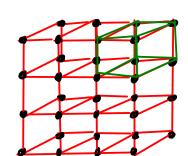

- have a disordered structure at the microscopic level.
- a very small amount of solids are completely amorphous, but quite a few plastics are at least partially amorphous.

2 CRYSTALLINE SOLIDS

- have a well-defined three dimensional structure at the microscopic level.
- structure is made up of a regular, repeating arrangement of points in space a CRYSTAL LATTICE

• • • The simplest repeating pattern that describes the entire crystal is called the UNIT CELL. It's outlined in GREEN here.

Here's a crystal lattice in three dimensions. This one is called a SIMPLE CUBIC lattice. This simple structure can be found in some solid metals like polonium. A polonium atom occupies each lattice point.

The unit cell, again, is highlighted in GREEN.

See pages 449-450 for more types of crystal systems and more unit cells.

- Natural crystals almost always have some DEFECTS in their structure.
 - Holes in the crystal lattice, where an atom should be but isn't
 - Misaligned planes in the crystal
 - Substitutions of one atom for another in the crystal lattice
- Often defects are undesirable, but not always:

Alumina: Al203

- clear / white in color
- usually used as the "grit" in cleaners like Comet and Soft Scrub!

ruby: A1203 with some A1
replaced with Cr

- red in color
- valuable gemstone!

- a SOLUTION is a HOMOGENEOUS MIXTURE.

—Uniform properties throughout!

- parts of a solution:

(SOLUTE(S)

- component(s) of a solution present in small amounts.

2)SOLVENT

- the component of a solution present in the GREATEST amount
- in solutions involving a solid or gas mixed with a LIQUID, the liquid is typically considered the solvent.
- solutions are usually the same phase as the pure solvent. For example, at room temperature salt water is a liquid similar to pure water.

- We traditionally think of solutions as involving gases or solids dissolved in liquid solvents. But ANY of the three phases may act as a solvent!

(I) GAS SOLVENTS

- Gases are MISCIBLE, meaning that they will mix together in any proportion.
- This makes sense, since under moderate conditions the molecules of a gas don't interact wth each other.
- Gas solvents will only dissolve other gases.

(2) LIQUID SOLVENTS

- Can dissolve solutes that are in any phase: gas, liquid, or solid.
- Whether a potential solute will dissolve in a liquid depends on how compatible the forces are between the liquid solvent and the solute.

3 SOLID SOLVENTS

- Solids can dissolve other solids, and occasionally liquids.
- Solid-solid solutions are called ALLOYS. Brass (15% zinc dissolved in copper) is a good example.
- AMALGAM is a solution resulting from dissolving mercury into another metal.

- When you discuss a solution, you need to be aware of:
 - what materials are in the solution
 - how much of each material is in the solution
- CONCENTRATION is the amount of one substance compared to the others in a solution. This sounds vague, but that's because there are many different ways to specify concentration!
- We will discuss four different concentration units in CHM 111:
 - (I) MASS PERCENTAGE

$$M$$
 or M

(3) MOLALITY

(4) MOLE FRACTION
