

## GAS FORMATION / OTHER MOLECULES

- There are a few other molecules that can be made with exchange-type chemistry.
- Most of these molecules are unstable and can break apart to form gases.

### - Formation of a weak acid:

- The formation of ANY weak acid in an exchange-type reaction can be a driving force.
- Some weak acids are unstable and can break apart into gas molecules.

... but how would you form carbonic acid in an exchange-type reaction?

acid + carbonate  $\text{CO}_3^{2-}$

OR

acid + bicarbonate  $\text{HCO}_3^-$

Formation of carbonic acid drives the reaction ... BUT ...

... but when we mix sulfuric acid and sodium bicarbonate, we observe BUBBLES. We need to write an equation that agrees with our observations. We know that carbonic acid decomposes, so we go ahead and put that into our equation.

Other molecules of interest:

$\text{H}_2\text{SO}_3$  : sulfurous acid - React an ACID with a SULFITE

$\text{H}_2\text{S}$  : hydrogen sulfide (gas) - React an ACID with a SULFIDE

A few more exchange examples:

PRECIPITATION of AgCl drives this reaction!

Formation of liquid WATER drives this NEUTRALIZATION reaction. Observe via release of heat!

Both 'products' in this equation are soluble ionic compounds - and exist in water as free ions. Since this is the same state they were in before they were mixed, there's no driving force - and NO REACTION!

Formation of carbonic acid and its decomposition into water and carbon dioxide gas drives this reaction. We will observe fizzing/bubbling as the reaction proceeds.

\* Transition metals DO NOT change their charge in exchange reactions!

126 OXIDATION / REDUCTION CHEMISTRY

- Exchange reactions involve ions pairing up, but the ions themselves are not formed in exchange reactions. Exchanges start with pre-existing ions.

... but the ions have to be produced somehow - through a chemistry that involves the transfer of electrons.

- oxidation / reduction chemistry ("redox" chemistry) involves transfer of electrons and can make ions.

Elemental,  
metallic  
aluminum.  
Uncharged!

Aluminum  
cation

These are called  
"half-reactions"

electron

oxidation: loss  
of electrons

reduction: gain of  
electrons

- oxidation and reduction always occur together. In other words, we can't just make free electrons using oxidation without giving them somewhere to go.

- Many of the types of reactions that we learned about in previous courses are redox reactions!

- COMBINATIONS (often but not always redox)

- DECOMPOSITIONS (often redox)

- SINGLE REPLACEMENT (always redox)

- COMBUSTION

A review of the reaction types we just mentioned:

## ① COMBINATION REACTIONS

- Reactions that involve two or more simple substances COMBINING to form a SINGLE product
- Often involve large energy changes. Sometimes violent!

Example:

## ② DECOMPOSITION REACTIONS

- Reactions where a SINGLE REACTANT breaks apart into several products

Example:

\* This reaction is NOT a combustion reaction, even though  $\text{O}_2$  is involved!

\* Combustion reactions CONSUME  $\text{O}_2$ , while this reaction PRODUCES  $\text{O}_2$

### 3 COMBUSTION REACTIONS

- Reactions of substances with MOLECULAR OXYGEN ( $O_2$ ) to form OXIDES.
- Combustion forms an OXIDE of EACH ELEMENT in the burned substance!

Oxide: a compound containing OXYGEN and one other element!

Examples:

This reaction can also be called a combination!  
Two reactants form a single product.

\* Combustion of hydrocarbons makes carbon dioxide and water, if enough oxygen is present. In low-oxygen environments, carbon monoxide is made instead!

## 4 SINGLE REPLACEMENT REACTIONS

- Reactions where one element REPLACES another element in a compound.
- Can be predicted via an ACTIVITY SERIES (p151, 9th edition)
- Form:  $A + BC \longrightarrow AC + B$  "A" and "B" are elements., often metals.
- Easy to spot, since there is an element "by itself" on each side of the equation.

Examples:
