102 Example:
How many milliliters of 6.00 M hydrochloric acid is needed to completely react with 25.0 g of sodium carbonate?

$$
2 \mathrm{HCl}(\mathrm{aq})+\mathrm{Na}_{2} \mathrm{CO}_{3}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(\ell)+\left(\mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{NaC}_{4}(\mathrm{aq})\right.
$$

1 - Convert 25.0 g of sodium carbonate to moles. Use FORMULA WEIGHT.
2 - Convert moles sodium carbonate to moles HCI. Use CHEMICAL EQUATION.
3 - Convert moles HCl to volume. Use MOLAR CONCENTRATION of HCl (and a L->mL conversion)
(3) 6.00 mol HEl $=\mathrm{L} \quad \mathrm{mL}=10^{-3} \mathrm{~L}$

$$
0.4717426172 \mathrm{mul} H C 1 \times \frac{L}{6.00 \mathrm{~mol} \mathrm{HCl}} \times \frac{m L}{10^{-3} \mathrm{~L}}=78.6 \mathrm{~mL} \mathrm{of} 6.00 \mathrm{~m} \mathrm{HCl}
$$

- When does a chemical reaction STOP?

$$
\begin{aligned}
& 2 \mathrm{Mg}_{\mathrm{g}}(\mathrm{~s})+\mathrm{O}_{2}(\mathrm{~g}) \xrightarrow{\Delta}>2 \mathrm{myO}_{\mathrm{m}}(\mathrm{~s}) \\
& \text { Magnesium } \\
& \text { powder }
\end{aligned}
$$

- When does this reaction stop? When burned in open air, this reaction stops when all the MAGNESIUM STRIP is gone. We say that the magnesium is LIMITING.
- This reaction is controlled by the amount of available magnesium
- At the end of a chemical reaction, the LIMITING REACTANT will be completely consumed, but there may be amount of OTHER reactants remaining. We do chemical calculations in part to minimize these "leftovers".

LIMITING REACTANT CALCULATIONS

- To find the limiting reactant, calculate how much product would be produced from ALL given reactants. Whichever produces the SMALLEST amount of product is the limiting reactant, and the smallest anount of product is the actual amount of product produced.
Example: $56.08 \quad 12.01 \Delta 4.10<$ - Formula weights

If you start with 100. g of each reactant, how much calcium carbide would be produced?

$$
\begin{aligned}
& \left.C: 12.01 \mathrm{~g} C=\operatorname{mal} C \mid 3 \operatorname{mol} C=\operatorname{mol} \mathrm{CaC}_{2}\right) 64-10 \mathrm{~g} C_{a} C_{2}=\mathrm{mol} \mathrm{CaC}_{2}
\end{aligned}
$$

114 grams of calcium carbide should be produced.. When 114 grams of the carbide is formed, all 100 grams of GaO have been used up, and the reaction stops. We still have leftover carbon, but there's nothing for it to react with! - no more product can be made!

We say that GaO is "limiting" (it controls how much product we make), and C is present "in excess".

## PERCENT YIELD

- Chemical reactions do not always go to completion! Things may happen that prevent the conversion of reactants to the desired/expected product!
(1) SIDE REACTIONS:

$$
\begin{aligned}
& \mathrm{C}+\mathrm{O}_{2} \longrightarrow \mathrm{CO}_{2} \left\lvert\, \begin{array}{l}
\text { This reaction occurs when there is a large amount } \\
\text { of oxygen available }
\end{array}\right. \\
& 2 \mathrm{C}+\mathrm{O}_{2} \longrightarrow 2 \mathrm{CO} \left\lvert\, \begin{array}{l}
\text {... while this reaction is more favorable in low-oxygen } \\
\text { environments! }
\end{array}\right. \\
& \text {... so in a low-oxygen environment, you may produce less carbon } \\
& \text { dioxide than expected! }
\end{aligned}
$$

(2) TRANSFER AND OTHER LOSSES

- When isolating a product, losses may occur in the process. Example: filtering

- Reactions may reach an equilibrium between prodcuts and reactants. We'll talk more about this in CHM 111. The net results is that the reaction will appear to stop before all reactants have been consumed!
- All of these factors cause a chemical reaction to produce LESS product than calculated. For many reactions, this difference isn't significant. But for others, we need to report the PERCENT YIELD.

$$
\begin{gathered}
\text { PERCENT } \\
\text { YIELD }
\end{gathered}=\frac{\text { ACTUAL YIELD }}{\text { THEORETICAL YIELD }} \times 100 \%
$$

... the percent yield of a reaction can never be greater than $100 \%$ due to conservation of mass! If you determine that a percent yield is greater than $100 \%$, then you've made a mistake somewhere - either in a calculation or in the experiment itself!

107

$$
\begin{aligned}
& 78.114 \mathrm{~g} / \mathrm{mol} \quad 123.111 \mathrm{~g} / \mathrm{mul}<\text { - Formula weights } \\
& 22.4 \mathrm{~g} \quad 31.6 \mathrm{~g} \mathrm{ACTUAL} \\
& \underset{\text { benzene }}{\mathrm{C}_{6} \mathrm{H}_{6}}+\underset{\text { nitric acid }}{\mathrm{HNO}_{3}} \longrightarrow \underset{\text { nitrobenzene }}{\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NO}_{2}}+\mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

22.4 grams of benzene are reacted with excess nitric acid. If 31.6 grams of nitrobenzene are collected from the reaction, what is the percent yield?
To get percent yield, we need to calculate the THEORETICAL YIELD of nitrobenzene, starting from the 22.4 g of benzene we reacted.

$$
\begin{aligned}
& 78.114 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{6}=\mathrm{mul} \mathrm{C}_{6} \mathrm{H}_{6} \quad \mathrm{~mol}_{6} \mathrm{H}_{6}=\mathrm{mol} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NO}_{2} \\
& 123 . \operatorname{lig} \mathrm{C}_{6} \mathrm{HSNO}_{2}=\mathrm{mul} \mathrm{C}_{6} \mathrm{H}_{\mathrm{SNO}}^{2} \\
& 22.4 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{6} \times \frac{\mathrm{mul} \mathrm{C}_{6} \mathrm{H}_{6}}{78.114 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{6}} \times \frac{\mathrm{mol}_{6} \mathrm{H}_{5} \mathrm{NO}_{2}}{\mathrm{~mol}_{6} \mathrm{H}_{6}} \times \frac{123.1 \mathrm{lg} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NO}_{2}}{\mathrm{mul} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NO}_{2}}= \\
& =35.3 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NO}_{2} \text { (theoretical yield) } \\
& \text { Percent yield }=\frac{\text { actual yield }}{\text { theor-yield }} \times 100 \%=\frac{31.6 \mathrm{~g}}{35.3 \mathrm{~g}} \times 100 \%=89.5 \%
\end{aligned}
$$

25.0 mL of acetic acid solution requires 37.3 mL of 0.150 M sodium hydroxide for complete reaction. The equation for this reaction is:

$$
\mathrm{NaOH}+\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2} \rightarrow \mathrm{NaC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}+\mathrm{H}_{2} \mathrm{O}
$$

What is the molar concentration of the acetic acid?
mol $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$

$$
\text { L Solution } \Leftarrow=25.0 \mathrm{~mL} \text { or } 0.0250 \mathrm{~L}
$$

Since we already know the volume of acetic acid solution, we need to find the moles of acetic acid. To do THAT, we'll start with the sodium hydroxide volume, since we can relate

$$
\begin{aligned}
& \text { that to moles (and then to the amount of acetic acid!)! } \\
& m L=10^{-3} L \quad O .150 \mathrm{~mol} \mathrm{NaOH}=L \quad \mathrm{mal} \mathrm{NaH}=\mathrm{molH} \mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2} \\
& 37.3 \mathrm{~mL} \times \frac{10^{-3} L}{m L} \times \frac{0.150 \mathrm{~mol} \mathrm{NaOH}}{L} \times \frac{\operatorname{molHC} \mathrm{H}_{2} \mathrm{O}_{2}}{\mathrm{mulNaH}}=0.005595 \mathrm{~mol}
\end{aligned}
$$

To get CONCENTRATION, we divide the moles by the volume of the acetic acid (in L )

$$
M=\frac{\text { mol } \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}}{L \text { Solution }}=\frac{0.005595 \mathrm{molHC}}{2} \mathrm{H}_{3} \mathrm{O}_{2}=\begin{aligned}
& 0.224 \mathrm{M} \\
& \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}
\end{aligned}
$$
