You can combine all three steps on one line if you like!

$$
\begin{equation*}
25.0 \mathrm{~g} \mathrm{Br}_{2} \times \frac{1 \mathrm{~mol} \mathrm{Br}_{2}}{159.80 \mathrm{~g} \mathrm{r}_{2}} \times \frac{2 \mathrm{~mol} \mathrm{Al}}{3 \mathrm{~mol} \mathrm{Br}} \times \frac{26.98 \mathrm{~g} \mathrm{Al}}{1 \mathrm{~mol} \mathrm{Al}}=2.81 \mathrm{~g} \mathrm{Al} \tag{1}
\end{equation*}
$$

You can solve the second part of the question using CONSERVATION OF MASS - since there's only a single product and you already know the mass of all reactants.

$$
\begin{aligned}
& 25.0 \text { y } \mathrm{Br}_{2} \quad \text { But... } \\
& +2.81 \mathrm{~g} \text { Ar } \quad \begin{array}{l}
\text { But.... } \\
+ \text {...hat would you have done to calculate the mass of aluminum }
\end{array} \\
& \text { bromide IF you had NOT been asked to calculate the mass of } \\
& \text { aluminum FIRST? } \\
& 25.0 \mathrm{~g} \mathrm{Br}_{2} \times \frac{1 \text { mol } \mathrm{Br}_{2}}{159.80 \mathrm{Br}_{2}} \times \frac{2 \mathrm{~mol} \mathrm{AlBr}_{3}}{3 \mathrm{~mol} \mathrm{Br}} \times \frac{266.694 \mathrm{gAl} \mathrm{Br}_{3}}{1 \mathrm{~mol} \mathrm{Al} \mathrm{Br}_{3}}=27.8 \mathrm{~g}
\end{aligned}
$$

${ }_{101}$ Example:
How many milliliters of 6.00 M hydrochloric acid is needed to completely react with 25.0 g of sodium carbonate?

$$
=\mathrm{HCl}(\mathrm{aq})+\mathrm{Na}_{2} \mathrm{CO}_{3}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\left(\mathrm{O}_{2}(g)+2 \mathrm{NaC}\right)(\mathrm{aq})
$$

1 - Convert 25.0 grams sodium carbonate to moles. Use FORMULA WEIGHT.
2 - Convert moles sodium carbonate to moles HCl . Use CHEMICAL EQUATION.
3 - Convert moles MCI to volume. Use MOLAR CONCENTRATION ( $6.00 \mathrm{moles} / \mathrm{L}$ )

$$
\begin{aligned}
&(1) \mathrm{Na}_{2} \mathrm{CO}_{3}: \quad N_{a}: 2 \times 22.99 \\
& C: 1 \times 12.01 \\
& 0: \frac{3 \times 16.00}{105.99} \mathrm{ga}_{2} \mathrm{CO}_{3}=\mathrm{mul} \mathrm{Na}_{2} \mathrm{CO}_{3} \\
& 25.0 \mathrm{~g} \mathrm{Na} \\
&
\end{aligned}
$$

(2) $2 \mathrm{~mol} \mathrm{HCl}=\mathrm{mol} \mathrm{Na}_{2} \mathrm{CO}_{3}$

$$
0.2358713086 \mathrm{~mol} \mathrm{Na} \mathrm{CO}_{3} \times \frac{2 \mathrm{~mol} \mathrm{HCl}}{\mathrm{~mol} \mathrm{Na}_{2} \mathrm{CO}_{3}}=0.4717426172 \mathrm{~mol} \mathrm{HCl}
$$

Example:
How many milliliters of 6.00 M hydrochloric acid is needed to completely react with 25.0 g of sodium carbonate?

$$
2 \mathrm{HCl}^{(a q)+\mathrm{Na}_{2} \mathrm{CO}_{3}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\left(\mathrm{O}_{2}(g)+2 \mathrm{NaC}_{1}(\mathrm{aq})\right.}
$$

1 - Convert 25.0 grams sodium carbonate to moles. Use FORMULA WEIGHT.
2 - Convert moles sodium carbonate to moles HCl . Use CHEMICAL EQUATION.
3 - Convert moles HCI to volume. Use MOLAR CONCENTRATION ( $6.00 \mathrm{moles} / \mathrm{L}$ )
(3) $6.00 \mathrm{mul} \mathrm{HCl}=\mathrm{L}$

$$
\begin{aligned}
& 0.4717426172 \mathrm{mul} \mathrm{HCl} \times \frac{L}{6.00 \mathrm{mul} \mathrm{HCl}}=\begin{array}{l}
0.0786 \mathrm{~L} \text { of } 6.00 \mathrm{~m} \mathrm{HCl} \\
\text { ․ but the problem asks us for } \mathrm{mL}, \\
\text { not L. Not a problem, though - } \\
\text { just convert L to } \mathrm{mL} .
\end{array} \\
& 0.0786 \mathrm{~L} \times \frac{\mathrm{mL}}{10^{-3} \mathrm{~L}}=78.6 \mathrm{~mL} \text { of } 6.00 \mathrm{~m} \mathrm{HCl}
\end{aligned}
$$

Tip: In most chemical calculation problems, we start by converting a given AMOUNT of substance to MOLES. We usually can't start with a conversion factor (a ratio, like molarity or formula weight).

- When does a chemical reaction STOP?

$$
\begin{aligned}
& 2 \mathrm{Mg}_{\mathrm{g}}(\mathrm{~s})+\mathrm{O}_{2}(\mathrm{~g}) \xrightarrow{\Delta}>2 \mathrm{myO}_{\mathrm{m}}(\mathrm{~s}) \\
& \text { Magnesium } \\
& \text { powder }
\end{aligned}
$$

- When does this reaction stop? When burned in open air, this reaction stops when all the MAGNESIUM STRIP is gone. We say that the magnesium is LIMITING.
- This reaction is controlled by the amount of available magnesium
- At the end of a chemical reaction, the LIMITING REACTANT will be completely consumed, but there may be amount of OTHER reactants remaining. We do chemical calculations in part to minimize these "leftovers".

LIMITING REACTANT CALCULATIONS

- To find the limiting reactant, calculate how much product would be produced from ALL given reactants. Whichever produces the SMALLEST amount of product is the limiting reactant, and the smallest anount of product is the actual amount of product produced.
Example: $56.08 \quad 12.01 \Delta 4.10<$ - Formula weights

If you start with 100. g of each reactant, how much calcium carbide would be produced?

$$
\begin{aligned}
& \left.\bar{C}: 12.01 \mathrm{~g} C=\operatorname{mol} C \mid 3 \mathrm{~mol} C=\operatorname{mol} \mathrm{CaC}_{2}\right) 64.10 \mathrm{~g} \mathrm{CaC}_{2}=\mathrm{mol} \mathrm{Cc}_{\mathrm{C}}
\end{aligned}
$$

114 grams of calcium carbide could be produced by the reaction. When we reach 114 grams of calcium carbide, we've consumed all of the GaO present, and the reaction stops. We say that GaO is LIMITING, and C is present in excess. There will still be C left over after the reaction stops.

## PERCENT YIELD

- Chemical reactions do not always go to completion! Things may happen that prevent the conversion of reactants to the desired/expected product!
(1) SIDE REACTIONS:

$$
\begin{aligned}
& \mathrm{C}+\mathrm{O}_{2} \longrightarrow \mathrm{CO}_{2} \left\lvert\, \begin{array}{l}
\text { This reaction occurs when there is a large amount } \\
\text { of oxygen available }
\end{array}\right. \\
& 2 \mathrm{C}+\mathrm{O}_{2} \longrightarrow 2 \mathrm{CO} \left\lvert\, \begin{array}{l}
\text {... while this reaction is more favorable in low-oxygen } \\
\text { environments! }
\end{array}\right. \\
& \text {... so in a low-oxygen environment, you may produce less carbon } \\
& \text { dioxide than expected! }
\end{aligned}
$$

(2) TRANSFER AND OTHER LOSSES

- When isolating a product, losses may occur in the process. Example: filtering

- Reactions may reach an equilibrium between prodcuts and reactants. We'll talk more about this in CHM 111. The net results is that the reaction will appear to stop before all reactants have been consumed!
- All of these factors cause a chemical reaction to produce LESS product than calculated. For many reactions, this difference isn't significant. But for others, we need to report the PERCENT YIELD.

$$
\begin{gathered}
\text { PERCENT } \\
\text { YIELD }
\end{gathered}=\frac{\text { ACTUAL YIELD }}{\text { THEORETICAL YIELD }} \times 100 \%
$$

... the percent yield of a reaction can never be greater than $100 \%$ due to conservation of mass! If you determine that a percent yield is greater than $100 \%$, then you've made a mistake somewhere - either in a calculation or in the experiment itself!

107

$$
\begin{aligned}
& 78.114 \mathrm{~g} / \mathrm{mul} \quad 123.111 \mathrm{~g} / \mathrm{mul}<\text { - Formula weights } \\
& \underset{\text { benzene }}{\mathrm{C}_{6} \mathrm{H}_{6}}+\underset{\text { nitric acid }}{\mathrm{HNO}_{3}} \longrightarrow \underset{\substack{\text { nitrobenzene }}}{31.6 \mathrm{~g} \text { ACTUAL }}+\mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

22.4 grams of benzene are reacted with excess nitric acid. If 31.6 grams of nitrobenzene are collected from the reaction, what is the percent yield?

To determine the percent yield, we need to calculate the THEORETICAL YIELD based on the amount of starting material - the 22.4 grams of benzene.

$$
\begin{aligned}
& 78.114 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{6}=\operatorname{mol} \mathrm{C}_{6} \mathrm{H}_{6} \quad \operatorname{mol} \mathrm{C}_{6} \mathrm{H}_{6}=\mathrm{mol} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NO}_{2} \\
& 123.1 \mathrm{ll} \mathrm{~g} \mathrm{C}_{6} \mathrm{Hs}_{\mathrm{S}} \mathrm{NO}_{2}=\mathrm{mul} \mathrm{l}_{6} \mathrm{HgNO}_{2} \\
& 22.4 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{6} \times \frac{\mathrm{mal}_{6} \mathrm{H}_{6}}{78.114 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{6}} \times \frac{\mathrm{mol} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NO}_{2}}{\mathrm{~mol}_{6} \mathrm{H}_{6}} \times \frac{123.1 \mathrm{l} \mathrm{gC}_{6} \mathrm{HgNO}_{2}}{\mathrm{mul} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NO}_{2}}= \\
& =35.3 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{\mathrm{S}} \mathrm{NO}_{2} \text { (theoretical yield) } \\
& \text { PERCENT YIELD }=\frac{\text { ACTUAL YIELD }}{\text { THEORETICAL YIELD }} \times 100 \%=\frac{31 . .6 g}{35,3 g} \times 10.6 / 3=89.5 \%
\end{aligned}
$$

108
25.0 mL of acetic acid solution requires 37.3 mL of 0.150 M sodium hydroxide for complete reaction. The equation for this reaction is:

$$
\mathrm{NaOH}+\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2} \rightarrow \mathrm{NaC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}+\mathrm{H}_{2} \mathrm{O}
$$

What is the molar concentration of the acetic acid?

$$
\frac{1 \text { mol } \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}}{\text { L Solution }}=25.0 \mathrm{~mL} \text { or } 0.0250 \mathrm{~L}
$$

Since we already know the volume of acetic acid, all we really have to find is the moles of acetic acid. We can't calculate that directly, but we CAN relate it to the amount of NaOH . So, start by finding out how many moles NaOH were reacted.

$$
\begin{aligned}
& m L=10^{-3} L \quad 0.150 \text { mum } \mathrm{NaOH}=L \quad \text { mol } \mathrm{NaOH}=\operatorname{mol} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2} \\
& 37.3 \mathrm{ml} \times \frac{10^{-3} L}{m L} \times \frac{0.150 \mathrm{mul} \mathrm{NaOH}}{L} \times \frac{\mathrm{mol} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}}{\operatorname{mol~} \mathrm{NaOH}}=0.005595 \mathrm{~mol}
\end{aligned}
$$

To get concentration, divide moles acid and volume OF THE ACID SOLUTION

$$
M=\frac{\text { mol } \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}}{L \text { solution }}=\frac{0.005595 \mathrm{~mol} \mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}}{0.0250 \mathrm{~L}}=0.224 \mathrm{MHC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}
$$
