ACID/BASE or NEUTRALIZATION reactions continued

- the driving force of these reactions is the formation of water molecules.

$$H^{+}(aq) + OH^{-}(aq) \longrightarrow H_{2}O(Q)$$
 Net ionic equation
From the acid From the base

H2504 (ay) + 2NaOH (ay)
$$\longrightarrow$$
 Na₂So₄ (aq)+2H₂O (l)
ions: H⁺ So₄²⁻ Na⁺ OH⁻ Potential Ma₂So₄ Infom the Driving force is formation of water molecules

- How can this reaction be detected?
 - pH detector (indicator paper, etc.)
 - do the products have similar chemical properties to the reactants?
 - release of heat!

... formation of water is usually accompanied by a release of heat

GAS FORMATION / OTHER MOLECULES

- There are a few other molecules that can be made with exchange-type chemistry.
- Most of these molecules are unstable and can break apart to form gases.
- Formation of a weak acid:
 - The formation of ANY weak acid in an exchange-type reaction can be a driving force.
 - Some weak acids are unstable and can break apart into gas molecules.

$$H_2(o_3 Lag) \longrightarrow H_2(l) + Co_2(g)$$
 Gas bubbles can leave solution!

... but how would you form carbonic acid in an exchange-type reaction?

$$H_2SO_4(a_4)+2NaH(O_3(a_4)) \rightarrow Na_2SO_4(a_4)+2H_2CO_3(a_4)$$
 $H^+SO_4^2-Na^+H(O_3^-)$

... but when we mix sulfuric acid and sodium bicarbonate, we observe BUBBLES. We need to write an equation that agrees with our observations. We know that carbonic acid decomposes, so we go ahead and put that into our equation.

$$H_2(O_3(aq)) \longrightarrow H_2O(l) + (O_2(q))$$

 $H_2SO_4(aq) + 2NaH(O_3(aq)) \rightarrow Na_2SO_4(aq) + 2H_2O(l) + 2(O_2(q))$

Other molecules of interest:

$$H_2SO_3$$
: sulfurous acid - React an ACID with a SULFITE

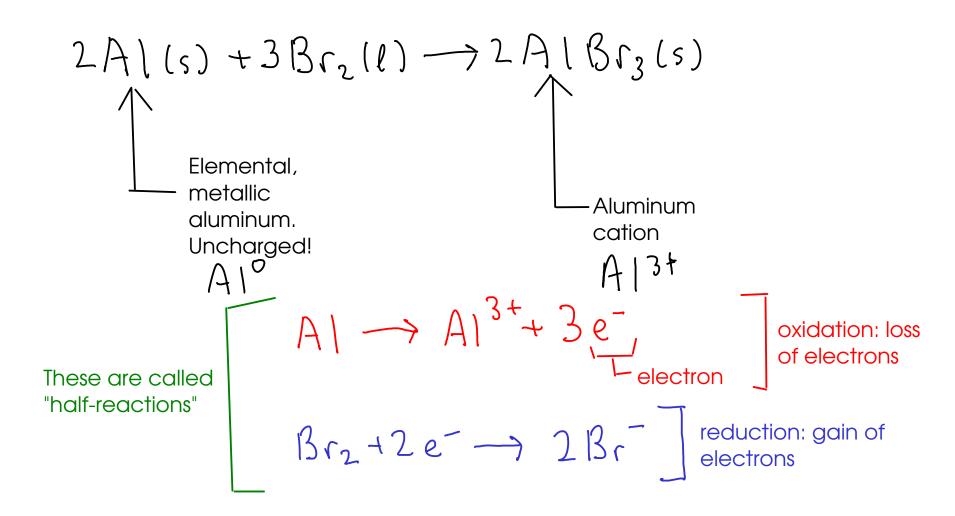

$$H_2So_3(ag) \rightarrow H_2O(\ell) + So_2(g)$$

 H_2S hydrogen sulfide (gas) - React an ACID with a SULFIDE

Formation of CARBONIC ACID MOLECULES (and their decomposition into WATER and CARBON DIOXIDE drive this reaction!)

- Exchange reactions involve ions pairing up, but the ions themseves are not formed in exchange reactions. Exchanges start with pre-existing ions.
- ... but the ions have to be produced somehow through a chemistry that involves the transfer of electrons.
 - oxidation / reduction chemistry ("redox" chemistry) involves transfer of electrons and can make ions.

- oxidation and reduction always occur together. In other words, we can't just make free electrons using oxidation without giving them somewhere to go.
- Many of the types of reactions that we learned about in previous courses are redox reactions!
 - COMBINATIONS (often but not always redox)
 - DECOMPOSITIONS (often redox)
 - SINGLE REPLACEMENT (always redox)

Cu (s) +2 Ag NO3 laq)
$$\rightarrow$$
 Cu (NO3)2 (aq) + 2 Ag (s)

Cu \rightarrow Cu²⁺ + 2e⁻ oxidation

2 Ag + 2e⁻ \rightarrow 2 Ag (s) reduction

net ini(\rightarrow Cu(s) + 2 Ag + (aq) \rightarrow (u²⁺(aq) + 2 Ag (s)

-COMBUSTION

2 Mg (s) + O2(g) \rightarrow 2 Mg O(s)

2 Mg (s) \rightarrow 2 Mg²⁺ + He⁻ oxidation

O2 (y) + He⁻ \rightarrow 20²⁻ reduction

A review of the reaction types we just mentioned:

- Reactions that involve two or more simple substances COMBINING to form a SINGLE product
- Often involve large energy changes. Sometimes violent!

Example:

$$2A|(s)+3Br_2(l)\longrightarrow 2A|Br_3(s)$$

1 <u>DECOMPOSITION REACTIONS</u>

- Reactions where a SINGLE REACTANT breaks apart into several products

Example:

$$2 H_{1}O_{2}(\ell) \longrightarrow 2 H_{2}O(\ell) + O_{2}(g)$$

- * This reaction is NOT a combustion reaction, even though O_2 is involved!
- * Combustion reactions CONSUME O_2 , while this reaction PRODUCES O_2

COMBUSTION REACTIONS

- Reactions of substances with MOLECULAR OXYGEN (O_2) to form OXIDES.
- Combustion forms an OXIDE of EACH ELEMENT in the burned substance!

- Form: AB + 0

$$AB + O_{2} \longrightarrow AO + BO$$

Oxide: a compound containing OXYGEN and one other element!

* Combustion of hydrocarbons makes carbon dioxide and water, if enough oxygen is present. In low-oxygen environments, carbon monoxide is made instead!

Examples:

$$(3 + 8 + 9) + 502(9) \longrightarrow 4 + 20(9) + 3(02(9))$$

$$2mg(s) + O_2(g) \longrightarrow 2mgO(s)$$

This reaction can also be called a combination! Two reactants form a single product.

SINGLE REPLACEMENT REACTIONS

- Reactions where one element REPLACES another element in a compound.
- Can be predicted via an ACTIVITY SERIES (p151, 9th edition)

- Form: A + BC - AC + B "A" and "B" are elements., often metals.

- Easy to spot, since there is an element "by itself" on each side of the equation.

Examples:
$$+1$$
 $\neq 2$ $\downarrow 3$ $\downarrow 4$ $\downarrow 2$ $\downarrow 3$ $\downarrow 4$ \downarrow

REDOX LANGUAGE

"oxidizer"

- "Oxidation" is loss of electrons, but an OXIDIZING AGENT is something that causes ANOTHER substance to lose electrons. An oxidizing agent is itself reduced during a redox reaction.
- "Reduction" is gain of electrons, but a REDUCING AGENT is something that causes ANOTHER substace to gain electrons. Reducing agents are themselves oxidized during a redox reaction.

$$2\cancel{A}(s) + 3\cancel{B}_{r_2}(l) \longrightarrow 2\cancel{A}(\cancel{B}_{r_3}(s))$$

Aluminum is OXIDIZED during this process. We say that metallic aluminum is a REDUCING AGENT!

Bromine is REDUCED during this process. We say that bromine is an OXIDIZING AGENT!

- * Strong oxidizers (oxidizing agents) can cause spontaneous fires if placed into contact with combustibles (safety issue!).
 - * Reactive metals tend to be REDUCING AGENTS, while oxygen-rich ions like NITRATES tend to be OXIDIZING AGENTS. HALOGENS (Group VIIA) also tend to be OXIDIZING AGENTS

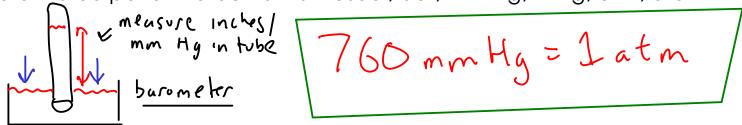

END OF CHAPTER 4 MATERIAL

- Gases differ from the other two phases of matter in many ways:
 - They have very low viscosity (resistance to flow), so they flow from one place to another very easily.
 - They will take the volume of their container. In other words, gas volumes are variable.
 - They are the least dense of all three phases.
 - Most gases are transparent, and many are invisible. thermal expansion!
 - Gases show a much larger change of volume on heating or cooling than the other phases.
 - Gases react to changes in temperature and pressure in a very similar way. This reaction often does not depend on what the gas is actually made of.

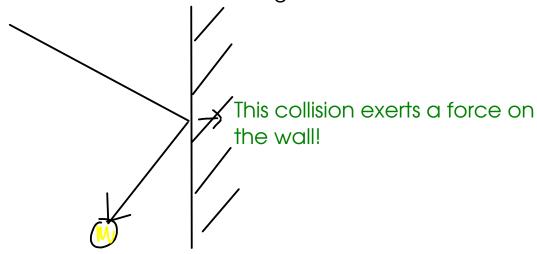

KINETIC THEORY

- is a way to explain the behavior of gases.
- views the properties of gases as arising from them being molecules in motion.

- Pressure: force per unit area. Units: Pascal, bar, mm Hg, in Hg, atm, etc.

- According to kinetic theory, pressure is caused by collisions of gas molecules with each other and the walls of the container the gas is in.

136- Temperature:

- a measure of the average kinetic energy of the molecules of the gas

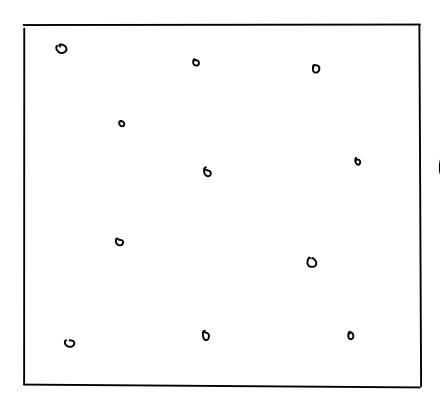

$$\frac{1}{2} \frac{m^2 \sqrt{2}}{\sqrt{\frac{velocity}{mass}}}$$

- The faster the gas molecules move, the higher the temperature!
- The temperature scales used when working with gases are ABSOLUTE scales.
 - ABSOLUTE: scales which have no values less than zero.

- KELVIN: metric absolute temperature scale.

THE KINETIC PICTURE OF GASES

Gas molecules are small compared to the space between the gas molecules!

LOW DENSITY!

- Gas molecules are constantly in motion. They move in straight lines in random directions and with various speeds.
- Attractive and repulsive forces between gas molecules are so small that they can be neglected except in a collision.
 - Each gas molecule behaves independently of the others.
- Collisions between gas molecules and each other or the walls are ELASTIC.
- (S) The average kinetic energy of gas molecules is proportional to the absolute temperature.

How does this picture explain the properties of gases?

- Gases expanding to fill their container? Agrees with kinetic picture, since gas molecules are independent
- Thermal expansion of gas at constant pressure? Agrees, because the container has to EXPAND to keep the pressure (from collisions) constant when the gas molecules move faster.
- Pressure increases with temperature at constant volume: Agrees, because the number and force of collisions increases with molecular speed.

GAS LAWS

- were derived by experiment long before kinetic theory, but agree with the kinetic picture!

Boyle's Law:

$$P_1V_1 = constant$$

$$P_2V_2 = constant$$

$$P_1V_1 = P_2V_2$$
True at constant temperature

Charles's Law:

True at constant pressure, and using ABSOLUTE temperature

$$\begin{array}{c|c}
\hline
\end{array}$$

$$\begin{array}{c|c}
\hline
\end{array}$$
True at constant pressure, and using ABSOLUTE temperature using ABSOLUTE temperature
