

Aluminum (Al): At atomic number 13, it is three electrons away from neon (Ne), and 5 electrons away from argon (Ar). Prediction: Aluminum will lose three electrons to form the cation Al<sup>37</sup>

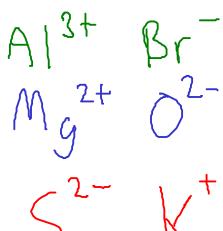

Bromine (Br): At atomic number 35, bromine is one electron away from krypton (Kr). Prediction: Bromine will gain one electron to form the anion Br

Strontium (Sr): At atomic number 38, strontium is two electrons away from krypton. Prediction: Strontium will lose two electrons to form the cation Sr

Find the formulas of:

- (1) an ionic compound containing AI and Br
- (2) an ionic compound containing Mg and O
- (3) an ionic compound containing S and K

Find the formula of:

\* an ionic compound containing AI and Br

Al Br

Find the formula of:

\* an ionic compound containing Mg and O

 $\frac{M_g^{24} O^{2-}}{M_g O}$ 

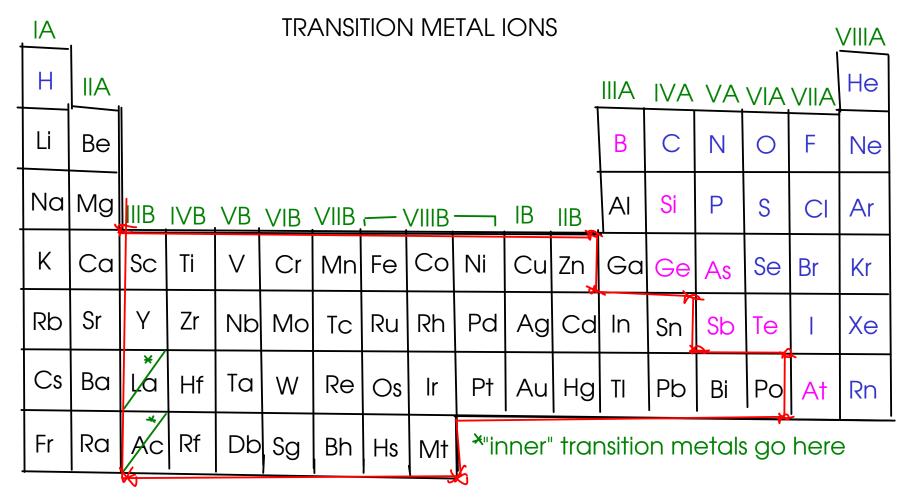

Find the formula of:

\* an ionic compound containing S and K

52- K+

7/25

Remember: Ionic formulas are ALWAYS written with the cation first!

The transition metals always form CATIONS!

However, many transition metals are capable of forming SEVERAL DIFFERENT CATIONS!

Example: Iron (Fe) forms two cations, depending on the situation: Fe or Fe

- So how do you know which cation you're dealing with? For now, you'll have to be told
- Either the chemical formula of an ionic compound or the name of an ionic compound can tell you what charge is on the transition metal cation.

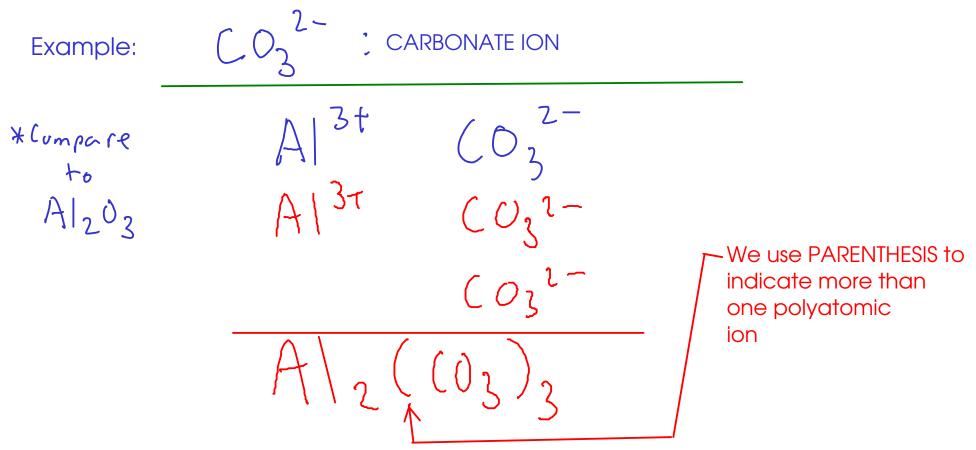

## Examples:

The form of iron in this compound is called "iron(III)", prononced "IRON THREE". The compound itself is called "iron(III) nitride".

The form of iron in this compound is called "iron(II)", prononced "IRON TWO". The compound itself is called "iron(II) nitride" - more on that name later!

### POLYATOMIC IONS

- Some MOLECULES can gain or lose electrons to form CATIONS or ANIONS. These are called POLYATOMIC IONS
- Polyatomic ions form ionic compounds in the same way that single-element ions do.

See the web site or page 63 - table 2.5 (9th ed) or table 2.6 (10th ed) - for a list of common polyatomic ions!

#### NAMES OF IONS

To properly discuss ions and ionic compounds, we have to know how to name them!
CATIONS

3 kinds:

Main group cations (metals that take only one charge when forming ions)

- The element's name is the same as the ion's name!

Transition metal cations (from metals that can form several cations)

- The CHARGE of the cation must be given. Use a ROMAN NUMERAL after the element name to indicate charge!

3† <u>Fe : "Iron(III) ion"</u>

Polyatomic cations

- Memorize list.

NH 4 : "ammonium ion"

#### **ANIONS**

#### 2 kinds

# Main-group nonmetals

- Use the STEM NAME of the element, then add "-ide" suffix

N<sup>3</sup>: "nitride" ion P<sup>3</sup>: "phosphide ion" S<sup>2</sup>: Sulfide Iun

O : "oxide ion" F : "fluoride ion"

## Polyatomic ions

- Memorize list.(see web site)

 $C_2H_3O_2$ : "acetate ion"  $SO_4$ : "sulfate ion"

 $NO_3$ : "nitrate ion"  $SO_3^2$  "sulfite ion"

NO<sub>2</sub>: "nitrite ion"

\* Polyatomic ions ending in "-ate" and "-ite" suffixes always contain oxygen! "-ate" ions have more oxygen atoms than their "-ite" counterparts.

#### NAMING IONIC COMPOUNDS

- The name of the compound is based on the name of the ions in the compound

- Cation first, anion second

Examples:

My (OH)2 /mágnesium hydroxide

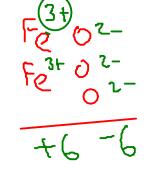

Naz S sodium sulfide

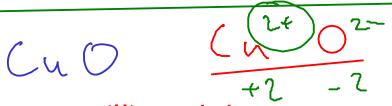

BeBrz

beryllium bromide

Fe 2 0 3

iron(III) oxide

copper(II) oxide

C 420

copper(I) oxide

Page 63 (9th edition): Chart of polyatomic ions Page 64 (10th edition)

<sup>\*</sup> Remember to include the Roman numeral for CHARGE when you're writing transition metal compound names!

NAMING IONIC COMPOUNDS

ammonium sulfide

iron(II) carbonate

titanium(IV) sulfide

barium phosph<u>ate</u>

barium phosphide
