MOLECULAR COMPOUNDS

- There are several kinds of molecular compound. We will learn to name two simple but important classes

BINARY MOLECULAR COMPOUNDS

- molecular compounds containing only two elements

2 ACIDS

- molecular compounds that dissolve in water to release $H^{\mathcal{T}}$ ions
- corrosive to metals (react with many to produce hydrogen gas)
- contact hazard: can cause chemical burns to eyes and skin
- sour taste
- turn litmus indicator RFD
- two kinds of acids:

usually Group VIIA

- contain hydrogen and one other element

- contain hydrogen, OXYGEN, and another element

BINARY MOLECULAR COMPOUNDS

- Named based on the elements they contain, plus prefixes to indicate the number of atoms of each element in each molecule

FIRST ELEMENT

- Add a GREEK PREFIX to the name of the element.
- Omit the "MONO-" (1) prefix if there is only one atom of the first element

SECOND ELEMENT

- Add a GREEK PREFIX to the STEM NAME of the element
- Add the suffix "-ide" (as if you were naming an anion)
- DO NOT omit the "mono-" prefix if there is only one atom of the second element

SEE COURSE WEB SITE FOR A LIST OF GREEK PREFIXES!

Examples:

BF3 boron

trifluoride

(1207

dichlorine hept(a)oxide C0

carbon monoxide C 0 2

carbon dioxide

dihydrogen monoxide (but we call this molecule "water")

carbon tetrachloride

CCly

iodine trichloride

 $\pm cl_3$

dinitrogen tetrafluoride

N2F4

MgCl2:

magnesium chloride, not magnesium dichloride. Why not? Because magnesium chloride is an IONIC compound, and is named with the system we talked about before.

How can we tell? metal/nonmetal compounds are almost always ionic!

106 ACIDS

(I) BINARY ACIDS

- named after the element (other than hydrogen) they contain
- common binary acids include a Group VIIA element
- named: "Hydro-" + STEM NAME OF ELEMENT+ "-ic acid"

Four common binary acids

HCI hydrochloric acid *most common binary acid!

HBC: hydrobromic acid

HT: hydroiodic acid

- (i) OXYACIDS
 - Easy to think about as HYDROGEN IONS combined with POLYATOMIC IONS
 - These acids are not true ionic compounds, but they interact with water to PRODUCE ions!
 - named based on the polyatomic ion they contain, with an ending change:
 - 1 ions ending in -ATE form acids ending in -IC
 - 1 ions ending in -ITE form acids ending in -OUS

H2 S04 based on sulfATE ion

sulfuric acid H₃ P₀ y
based on
phosphATE ion

phosphoric acid

H2^{SO}3 based on sulfITE ion

sulfurous acid HNO3 based on nitrATE

nitric acid acetic acid based on ACETATE ion

H (2H302

carbonic acid

bused on carbonate

Ht (032
Ht

H2(03

nitrous acid .

bused on nitrite

Ht NO2

HN02

* The number of hydrogen ions to add to the polyatomic to make the acid equals the charge of the polyatomic. - You need to be able to tell, by looking at a name OR a formula, what kind of compound you are working with!

DON'T GET THE NAMING SYSTEMS MIXED UP! EACH KIND OF COMPOUND IS NAMED WITH ITS OWN SYSTEM!

FROM A CHEMICAL NAME

- If the name has a Roman numeral, the name of a metal, or "ammonium", the compound is likely IONIC
- If the name has a Greek prefix, the compound is BINARY MOLECULAR
- If the name contains the word "acid":
 - ... and starts with "hydro-", then the compound is a BINARY ACID
 - ... and does not start with "hydro-", the compound is an OXYACID

1 FROM A CHEMICAL FORMULA

- if the formula contains a metal or the NH_4^+ ion, it is likely IONIC
 - H20 H202
- If the formula starts with H and is not either water or hydrogen peroxide, the compound is likely an ACID. Which kind?
 - BINARY ACIDS contain only two elements
 - OXYACIDS contains oxygen
- If the formula contains only nonmetals (and is not an ammonium compound or an acid), the compound is likely MOLECULAR

Examples:

PC/3: BINARY MOLECULAR Name: phosphorus trichloride
$$NH_4$$
 C1: IONIC (ammonium ion) Name: ammonium chloride NH_4 C1: Name: ammonium chloride NH_4 Name: ammonium chloride NH

CHEMICAL EQUATIONS

- are the "recipes" in chemistry
- show the substances going into a reaction, substances coming out of the reaction, and give other information about the process

$$Mg(l_2(aq) + 2AgNO_3(aq) \xrightarrow{"yields"} 2Ag(l_{(s)} + Mg(NO_3)_2(aq)$$

REACTANTS - materials that are needed for a reaction

PRODUCTS - materials that are formed in a reaction

COEFFICIENTS - give the ratio of molecules/atoms of one substance to the others

PHASE LABELS - give the physical state of a substance:

- (s) -solid
- (I) liquid
- (g) gas

(aq) - aqueous. In other words, dissolved in water
