A solution of 2.500g of unknown dissolved in 100.0 g of benzene has a freezing point of 4.880 C. What is the molecular weight of the unknown?

$K_{f,\,benzene} = 5.065\ ^{\circ}C/m$, $T_{f,\,benzene} = 5.455^{\circ}C$ (see p500 9th, p509, 10th)

$\Delta T_f = K_f \times C_m$

$K_f = 5.065\ ^{\circ}C/m$

$\Delta T_f = 5.455^{\circ}C - 4.880^{\circ}C = 0.575\ ^{\circ}C$

$C_m = \frac{\text{mol unknown}}{\text{kg benzene}}$

To find molecular weight, we need to find out how many moles of unknown we dissolved.

First, calculate the MOLAL CONCENTRATION of the solution!

Find Cm to find the moles of unknown!

$0.575\ ^{\circ}C = (5.065\ ^{\circ}C/m) \times C_m$

$C_m = 0.113524186\ m = \frac{0.113524186 \text{ mol unk}}{\text{kg benzene}}$

To find MOLES UNKNOWN, multiply the MASS BENZENE by the MOLAL CONCENTRATION

$0.1000 \text{ kg benzene} \times \frac{0.113524186 \text{ mol unk}}{\text{kg benzene}} = 0.0113524186 \text{ mol unk}$

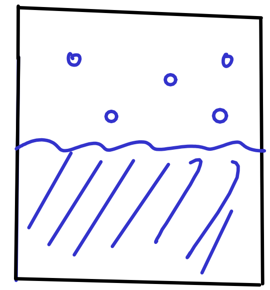
MOLECULAR WEIGHT is mass per mole, so ...

$MW = \frac{\text{mass unknown}}{\text{mol unknown}} = \frac{2.500\text{g}}{0.0113524186 \text{ mol unk}} = 220.\ \text{g/mol}$

VAPOR PRESSURE LOWERING

- Described by RAOULT'S LAW

$$P_A = P_A^* \times X_A$$



P_A = partial pressure of the VAPOR of solvent molecules.

- X_A: mole fraction of component A
- P_A^*: vapor pressure of pure component A (depends on temperature)
- P_A: partial pressure of component A in a solution

... but component "A" above is actually the SOLVENT. If we want to describe this as a colligative property, we want to express Raolt's law in terms of the SOLUTE! Assuming a two-component mixture, we get...

$$\Delta P = P_A^* \times X_B$$

- X_B: mole fraction of component B (the SOLUTE in a two-component mixture)
- ΔP: Vapor pressure lowering. This is the DECREASE in the vapor pressure of the solvent due to the presence of solute.

BOILING POINT ELEVATION

- Since the vapor pressure is lowered by the presence of a solute, AND since boiling occurs when the vapor pressure of a liquid equals the external pressure - solutes also cause BOILING POINT ELEVATION.

- The equation for boiling point elevation looks almost exactly like the equation for the freezing point depression, and is used in almost the same way.

$$\Delta T_b = K_b \times c_m$$

- c_m: concentration of solute (molality)
- K_b: Boiling point elevation constant (for SOLVENT) (p500, 9th; p509, 10th)
- ΔT_b: Boiling point elevation: The amount the boiling temperature is RAISED by the solute.

What is the boiling point of a solution that contains 2.817 g of molecular sulfur S_8) dissolved in 100.0 grams of acetic acid?

$T_b = 118.5°C$ $K_b = 3.08°C/m$ (see p500 for data) p509, 10th

---

$\Delta T_b = K_b \times C_m$ (3.08°C/m) | $C_m = \frac{mol\ S_8}{kg\ HC_2H_3O_2}$ 0.1000 kg

Find moles sulfur, then use that to find the MOLAL CONCENTRATION of the solution.

S_8: 8 x 32.07 = 256.56 g S_8 = mol S_8

$$2.817\,g\,S_8 \times \frac{mol\ S_8}{256.56\,g\,S_8} = 0.01097988777\ mol\ S_8$$

Find Cm:

$$C_m = \frac{0.01097988777\ mol\ S_8}{0.1000\ kg\ HC_2H_3O_2} = 0.1097988775\ m$$

Find BOILING POINT ELEVATION

$$\Delta T_b = K_b \times C_m = (3.08°C/m)(0.1097988775\ m) = 0.3382°C$$

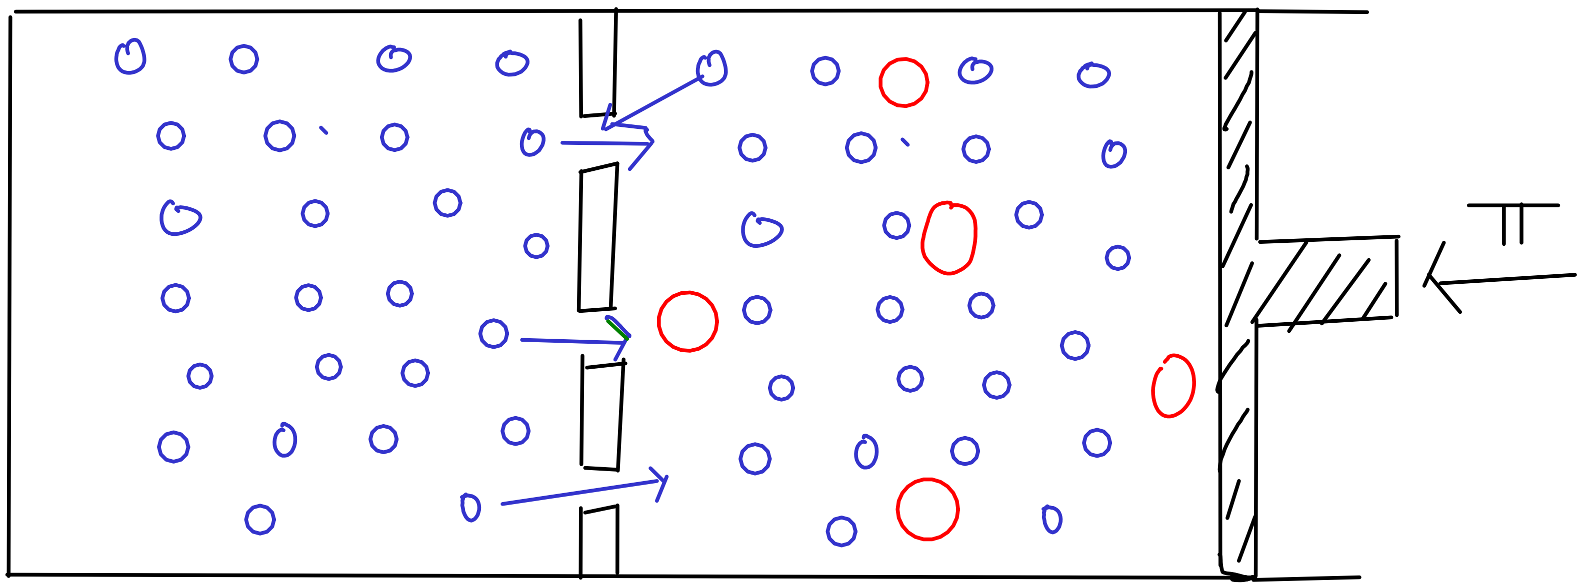
Find new boiling point by adding deltaT to the original boiling point:

$$T_{b,solution} = 118.5°C + 0.3382°C = \boxed{118.8°C}$$

OSMOTIC PRESSURE

permits flow of solvent, but not solute particles

- OSMOSIS: the flow of solvent molecules through a SEMIPERMEABLE membrane to equalize concentration of solute on each side of the membrane.



The rate of solvent migration towards the RIGHT is greater than that towards the LEFT.

If you apply enough pressure to the piston, osmosis will not occur. This pressure is called the OSMOTIC PRESSURE

$$\pi = M \times R \times T$$

- T: temperature
- R: ideal gas constant
- M: molar concentration of solute

IONIC COMPOUNDS and colligative properties

- Ionic compounds DISSOCIATE in water into their component ions. Each ion formed can act as a solute and influence the colligative properties!

$$NaCl(s) \longrightarrow Na^{+}(aq) + Cl^{-}(aq)$$

2 ions!

... so the concentration of IONS here is TWICE the nominal NaCl concentration.

$$CaCl_2(s) \longrightarrow Ca^{2+}(aq) + 2\,Cl^{-}(aq)$$

3 ions!

... so the concentration of IONS here is THREE TIMES the nominal calcium chloride concentration.

- Ions interact with each other in solution, so unless an ionic solution is DILUTE, the effective concentrations of ions in solution will be less than expected. A more advanced theory (Debye-Huckel) covers this, but we'll assume that our solutions are dilute enough so that we can use the concentration of the ions in solution to determine the colligative properties!

If you are at an altitude high enough for the boiling point of water to be 95.00 C, what amount of sodium chloride would you need to add to 1.000 kg of water to raise the boiling point to 100.00 C?

$K_b = 0.512\ ^{\circ}C/m$ NaCl: 58.443 g/mol

$\Delta T_b = K_b \times C_m$

$K_b = 0.512\ ^{\circ}C/m$

$\Delta T_b = 100.00^{\circ}C - 95.00^{\circ}C = 5.00^{\circ}C$

$C_m = \frac{\text{mol ions}}{\text{kg } H_2O}$] 1.000 kg

Find Cm (molal concentration of IONS)

$5.00^{\circ}C = 0.512\ ^{\circ}C/m \times C_m$; $C_m = 9.765625\ \underline{m}$ ions

FInd moles IONS ...

$1.000 \text{ kg water} \times \frac{9.765625 \text{ mol ions}}{\text{kg water}} = 9.765625 \text{ mol ions}$

$NaCl(s) \rightarrow Na^+(aq) + Cl^-(aq)$, so mol NaCl = 2 mol ions

Find moles sodium chloride, then convert to mass for weighing.

$9.765625 \text{ mol ions} \times \frac{\text{mol NaCl}}{2 \text{ mol ions}} \times \frac{58.443 \text{ g NaCl}}{\text{mol NaCl}} = \boxed{285 \text{ g NaCl}}$
