Converting from one unit to another

We will use the method of dimensional analysis, sometimes called the factor-label method. ... or, the "drag and drop" method!

Dimensional analysis uses conversion factors to change between one unit and another

What's a conversion factor? A simple equality.

Conversion factors in metric

In the metric system, conversion factors between units may always be made from the metric prefixes!

For example, "
$$K_{10}$$
" means 10^{3}
 $K = 10^{3}$

So

 $Kg = 10^{3}$
 $Km = 10^{3}$
 $KS = 10^{3}$
 $KS = 10^{3}$
 $KS = 10^{3}$
 $KL = 10^{3}$

How do we actually USE a conversion factor?

Convert 15.75 m to cm
$$= 10^{-2}$$
 m If $X = 2$, then $\frac{X}{2} = \frac{1}{2}$ IS.75 / EF $= 2$... on TI-83

* This fraction equals one, so multiplying by it does not change the VALUE of the number, only its UNITS!

Convert 0.01893 kg to g
$$\frac{10^3}{9}$$
 = $\frac{10^3}{18.93}$ = $\frac{10^3}{18.93}$ = $\frac{10^3}{18.93}$

DRAG AND DROP

- Drag the part of the factor that contains the unit you want to get rid of (cancel out) to the BOTTOM.
- Then, drag the other half of the factor to the TOP

$$mg = 10^{-3}$$

$$Kg = 10^{3}g$$

$$\frac{10^{-3}}{mg} \times \frac{Kg}{mg} = 0.0145 Kg$$

Convert 0.147 cm² to m²

$$(m-1)^{-2}$$
 <- Don't use squared or cubed units when

making a factor!

$$0.147 \text{ cm}^2 \times \frac{10^{-2} \text{m}}{\text{cm}} \times \frac{10^{-2} \text{m}}{\text{cm}} = \frac{1.47 \times 10^{-5} \text{m}^2}{(0.0000141) \text{m}^2}$$

For squared and cubed units, use each conversion factor two (for squared) or three (for cubed) times. Think of squared and cubed units this way:

$$(m^2 = cm \times cm)$$

 $cm^3 = cm \times cm \times cm$

... and it should make sense.

8.45 kg to mg
$$\frac{10^{3}g}{\text{Kg}} \times \frac{10^{3}g}{10^{-6}} = \frac{10^{-6}g}{8.45 \times 10^{9} \text{mg}}$$
(845 00000000 mg)

88100 kHz to MHz

$$KHz = 10^{3}Hz$$
 $MHz = 10^{6}Hz$
 $88100 KHz \times \frac{10^{3}Hz}{KHz} \times \frac{MHz}{10^{6}Hz} = 88.1 MHz$

Convert 38.47 in to m, assuming 2.54 cm = 1 in
$$2.54$$
 cm = 10^{-2} m

Convert 12.48 km to in

12.48
$$\frac{10^3 \text{m}}{\text{km}} \times \frac{10^3 \text{m}}{10^{-2} \text{m}} \times \frac{\text{in}}{2.54 \text{cm}} = \frac{491300 \text{in}}{491300 \text{in}}$$

Accuracy and Precision

- two related concepts that you must understand when working with measured numbers!

Accuracy

- how close a measured number is to the CORRECT (or "true") value of what you are measuring
- "Is it right?"
- checked by comparing measurements against a STANDARD (a substance or object with known properties)

Precision

- how close a SET of measured numbers are to EACH OTHER
- "Can I reproduce this?"
- checked by repeated measurements
