

TYPES OF REACTIONS

- There are many kinds of chemical reaction. We'll begin with three types:

① PRECIPITATION REACTIONS

② ACID-BASE REACTIONS

③ OXIDATION-REDUCTION REACTIONS

- Not every possible mixture of chemicals will react. Most reactions require a DRIVING FORCE, which is usually some stable substance that forms to push a reaction forward.

PRECIPITATION REACTIONS

- Driven by the formation of an insoluble ionic compound.

When you're trying to complete a precipitation reaction:

- ① Write the IONS that form when the reactants are dissolved.
- ② Make NEW compounds by pairing up cations with anions. Don't forget that the positive and negative charges must balance each other out!
- ③ Use the solubility rules to determine the PHASE of each new compound - solid or aqueous.
- ④ Balance the overall equation.

$\text{Mg}(\text{C}_2\text{H}_3\text{O}_2)_2$... dissolves in water

NaCl ... dissolves in water

So, no solid forms here. All possible combinations of these four ions result in compounds that dissolve readily in water.

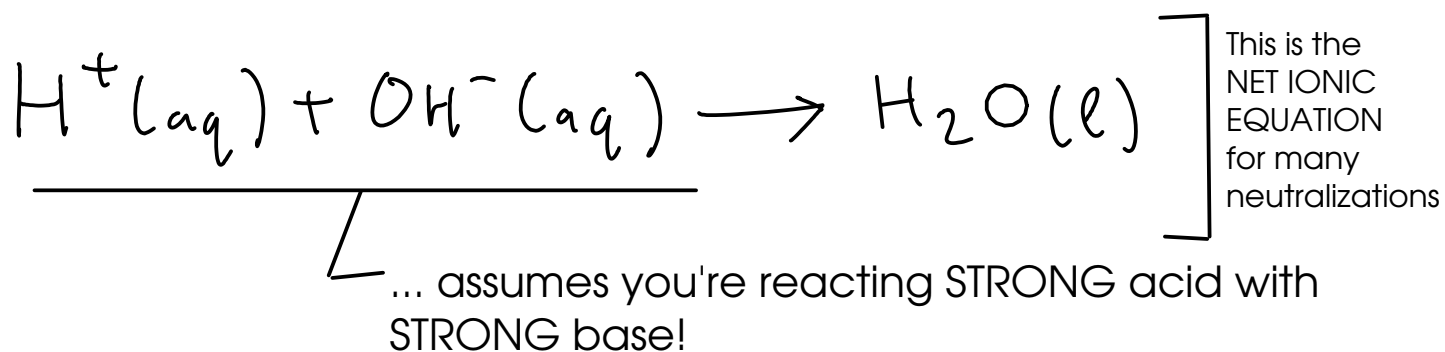

* We will learn about other driving forces than the formation of solid, but these driving forces do not apply to this reaction

ACID/BASE REACTIONS (also called NEUTRALIZATION REACTIONS)

- There are several stable molecules that may be formed in double replacement reactions, but the most common is WATER!
- Double replacement reactions that form water are also called "neutralizations"

* To make water (H_2O), you need a source of hydrogen ion (H^+) and hydroxide ion (OH^-)

ACIDS

- compounds that release hydrogen ion (H^+), when dissolved in water.

Properties of acids:

- Corrosive: React with most metals to give off hydrogen gas
- Cause chemical burns on contact
- Taste sour (like citrus - citric acid!)
- Changes litmus indicator to RED

BASES

- Substances that release hydroxide ion (OH^-) when dissolved in water

Properties of bases:

- Caustic: Attack and dissolve organic matter (think lye, which is NaOH)
- Cause skin/eye damage on contact
- Taste bitter
- changes litmus indicator to BLUE

Due to the dissolving action of base on your skin, bases will feel "slippery". The base ITSELF is not particularly slippery, but what's left of your skin IS!

ACID/BASE or NEUTRALIZATION reactions continued

- the driving force of these reactions is the formation of water molecules.

This reaction is driven by the formation of WATER MOLECULES!

- How can this reaction be detected?

- pH detector (indicator paper, etc.)
- do the products have similar chemical properties to the reactants?
- release of heat!

... formation of water is usually accompanied by a release of heat
